#### Abstract

When $\mathrm{Pt}(\mathrm{COD}) \mathrm{Cl}_{2}$ was treated with sodium amalgam in the presence of aromatic isocyanide ( RNC , $\mathrm{R}=2,6-\mathrm{Me}_{2} \mathrm{C}_{6} \mathrm{H}_{3}(\mathrm{Xyl})$ or $2,4,6-\mathrm{Me}_{3} \mathrm{C}_{6} \mathrm{H}_{2}(\mathrm{Mes})$ ) and diphosphine with long methylene chain (diphos $-\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{CH}_{2}\right)_{n} \mathrm{PPh}_{2}, n=5$ (dpppn) or 6 (dpphex)), two kinds of $\mathrm{Hg}-\mathrm{Pt}$ mixed metal clusters, $\left[\mathrm{H}_{\mathrm{g}_{2}} \mathrm{Pt}_{6}-\right.$ (diphos) $\left.)_{2}(\mathrm{RNC})_{8}\right]$ (2) and $\left[\mathrm{Hg}_{2} \mathrm{Pt}_{6}(\text { diphos })_{3}(\mathrm{RNC})_{6}\right](3)$, were obtained. The structure of $\mathbf{3 b}(\mathrm{R}=\mathrm{Xyl}$, diphos $=$ dpphex) was determined by an $X$-ray analysis to be a cage-type cluster where a $\mathrm{Hg}_{2}$ unit was incorporated into a trigonal-anti-prismatic platinum core, two $\mathrm{Pt}_{3}$ triangles being supported by three dpphex ligands (close-type). The cluster 2 was assumed to have an incomplete cage-type structure (open-type), and was converted to close-type 3 by treatment with an equivalent diphosphine ligand. When dppb ( $n=4$ ) was used, an open-type mixed metal cluster in which one mercury atom was captured, $\left[\mathrm{HgPt}_{6}(\mathrm{dppb})_{2}(\mathrm{RNC})_{8}\right](4)$, was obtained as the sole product.

Metal clusters are of interest as a potential bridge between homogeneous and heterogeneous catalytic reactions [1]. We reported that treatment of dichlorobis( 2,6 -xylyl isocyanide) platinum(II) with sodium amalgum gave the high nuclearity cluster, $\mathrm{Pt}_{7}\left(2,6-\mathrm{Me}_{2} \mathrm{C}_{6} \mathrm{H}_{3} \mathrm{NC}\right)_{12}$ [2]. A similar reduction in the presence
 [ $\mathrm{HgPt}_{6}\left(2,6-\mathrm{Me}_{2} \mathrm{C}_{6} \mathrm{H}_{3} \mathrm{NC}\right)_{12}$ ] (1) [3]. Electrochemical reduction of $\mathrm{PtCl}_{2}(\mathrm{RNC})_{2}$ and $\left[\mathrm{Pt}(\mathrm{RNC})_{4}\right]^{2+}$ gave di- and trinuclear complexes, $\mathrm{Pt}_{2} \mathrm{Cl}_{2}(\mathrm{RNC})_{4}$, $\left[\mathrm{Pt}_{2}(\mathrm{RNC})_{6}\right]^{2+}$, and $\left.\mathrm{Pt}_{3}(\mathrm{RNC})_{8}\right]^{2+}$, whose selectivities varied depending on the charge controlled conditions [4,5]. Recently, di- and trinuclear platinum complexes

[^0]containing isocyanides and chelating diphosphines (diphos $=\mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{CH}_{2}\right)_{n} \mathrm{PPh}_{2}$ $2 \leq n \leq 4$ ) have been prepared by the electrochemical techniques, in which the length of the methylene carbon chain of diphos influenced their stereochemistry [6]. In particular, when the charge of $1.5 \mathrm{~F} / \mathrm{mol}$ of $\left[\operatorname{Pt}(\mathrm{RNC})_{2}(\mathrm{dppp})\right]^{2+}(n=3)$ was passed, novel linear triplatinum complexes involving a coordinatively "naked" platinum center were obtained. Here, we introduce diphosphines with long methylene chains $(4 \leq n \leq 6)$ to the platinum-isocyanide system, and report on the synthesis and characterization of novel cage-type mixed-metal clusters supported by diphosphines.

A mixture of $\mathrm{Pt}(\mathrm{COD}) \mathrm{Cl}_{2}, \mathrm{RNC}$, diphos, and $\mathrm{NH}_{4} \mathrm{PF}_{6}\left(\mathrm{R}=2,6-\mathrm{Me}_{2} \mathrm{C}_{6} \mathrm{H}_{3}(\mathrm{XyI})\right.$ or $2,4,6-\mathrm{Me}_{3} \mathrm{C}_{6} \mathrm{H}_{2}$ (Mes), diphos $=$ dpppn $(n=5)$ or dpphex $(n=6)$ ) was treated with $\mathrm{Na}-\mathrm{Hg}$ at room temperature for several hours. The dark green solution was chromatographed on deactivated alumina. After work-up of the eluate, the residue was recrystallized from benzene / hexane to give two kinds of dark green crystals ( 2 and 3), formulated as $\left[\mathrm{Hg}_{2} \mathrm{Pt}_{6}(\text { diphos })_{2}(\mathrm{RNC})_{\mathrm{s}}\right] \cdot \mathrm{C}_{6} \mathrm{H}_{6}$ (2a. diphos $=$ dppprı, $\mathrm{R}=$ $2,4,6-\mathrm{Me}_{3} \mathrm{C}_{6} \mathrm{H}_{2} 7 \%$; 2b, diphos $=$ dpphex, $\mathrm{R}=2,6-\mathrm{Me}_{2} \mathrm{C}_{6} \mathrm{H}_{3} 5 \%$ ) and $\left[\mathrm{Hg}_{2} \mathrm{Pt}_{6}\right.$ (diphos) $3_{3}\left(\mathrm{RNC}_{6}\right) \cdot \mathrm{C}_{6} \mathrm{H}_{6} \quad$ (3a, diphos $=$ dpppn, $\mathrm{R}=2.4,6-\mathrm{Me}_{3} \mathrm{C}_{6} \mathrm{H}_{2} \quad 10 \% ; 3 \mathrm{~b}$, diphos $=$ dpphex, $\mathrm{R}=2,6-\mathrm{Me}_{2} \mathrm{C}_{6} \mathrm{H}_{3}, 38 \%$ ) $\left[7^{*}, 8^{*}\right]$. The IR spectrum of 3 indicated the presence of only bridging isocyanide groups $(p(\mathrm{C}=\mathrm{N})$ co. $1840 \mathrm{~m}, 1710$ $\mathrm{cm}^{-1}$ ). The electronic absorption spectrum showed a characteristic absorption around 650 nm , similar to that of $\mathbf{1}$. To clarify the structure, an X-ray analysis of $\mathbf{3} \mathbf{b}$ was undertaken (Fig. 1) $\left[9^{*}\right]$. The molecule consists of two triangular P 1 : units which are connected by three diphosphines (dpphex). The six isocyanide molecules act as bridging ligands in each triangular unit. Two mercury atoms are captured in an anti-trigonal-prismatic cage (called "close-type"). A similar cluster $\left[\mathrm{Hg}_{2} \mathrm{Pt}_{0}(\mu\right.$ -$\left.\mathrm{CO})_{6}\left(\mathrm{PPh}^{-} \mathrm{Pr}_{2}\right)_{6}\right]$ (5), in which two Hg atoms were sandwiched between two $\mathrm{Pt}_{3}$ units, has been reported by Albinati [10]. The $\mathrm{Hg}-\mathrm{Hg}$ distance of $2.872(7) \AA$ is significantly shorter than that of the carbonyl cluster $5(3.225 \mathrm{~A})$ and slightly shorter than is found in the crystalline $\alpha$ form of metallic $\mathrm{Hg}(2.90 \AA$ ), but longer than those of $\mathrm{Hg}_{2} \mathrm{X}_{2}$ salts for $\mathrm{X}=$ halide $(2.49-2.69 \AA$ ) [11]. The average $\mathrm{Pt}-\mathrm{Hg}$ and Pt-Pt distances are $2.950 \AA$ and $2.664 \AA$, respectively, compared with those found in the clusters $\mathbf{1}$ and 5 . Preliminary extended Hückel MO calculations were carried out on a model compound $\left[\mathrm{Hg}_{2} \mathrm{Pt}_{6}(\mu-\mathrm{CNH})_{6}\left(\mathrm{PH}_{3}\right)_{6}\right]\left(D_{3 /}\right.$ symmetry $)$ [12]. On the basis of the long $\mathrm{Hg}-\mathrm{Hg}$ distance comparable to that of metallic mercury. the molecular orbital analysis was simplified to an interaction of $\left[\mathrm{Pt}_{3}(\mu\right.$ $\left.\mathrm{CNH})_{3}\left(\mathrm{PH}_{3}\right)_{3}\right]_{2}^{0}$ with $\mathrm{Hg}_{2}{ }^{0}\left(d_{\mathrm{Hg}-\mathrm{Hg}}=2.87 \AA\right.$ A $)$. The HOMO is derived from a repulsive interaction between the filled $\mathrm{Pt} d$ orbitals in the triangular plane (depicted as I for the single $\mathrm{Pt}_{3}$ triangle in Fig. 2) and the filled $\sigma^{*}$ orbital ( Hg 65 ), and is stabilized by a bonding interaction with the empty orbital composed of ( $\mu$-CNH) $\pi^{*}$ and $\mathrm{Pt} p_{z}$ (depicted as $\mathbf{I I}$ in Fig. 2). From these, the $\mathrm{Hg}-\mathrm{Hg}$ interaction is presumed to be weak, although the repulsive character between Hg atoms is somewhat relaxed through the empty ( $\mu-\mathrm{CNH}$ ) $\pi^{*}$ and $\mathrm{Pt} p$ orbitals.

Heating of cluster 3 in refluxing toluene led to a recovery of the starting material, whereas a similar treatment of 1 extracted mercury from the prismatic

Fig. 1. (a) A perspective drawing of $\left[\mathrm{Hg}_{2} \mathrm{Pt}_{6}(\mathrm{dpphex})_{3}(\mathrm{XylNC})_{6}\right]$ (3b). (b) Cluster core of 3b. Some selected bond distances and angles: $\mathrm{Hg}-\mathrm{Hg}^{\prime} 2.872(7), \mathrm{Hg}-\mathrm{Pt}(1) 2.980(6), \mathrm{Hg}-\mathrm{Pt}(2) 2.993(6), \mathrm{Hg}-\mathrm{Pt}(3)$ 2.878(6), $\operatorname{Pt}(1)-\operatorname{Pt}(2) 2.664(3), \operatorname{Pt}(1)-\mathrm{Pt}(3) 2.672(4), \mathrm{Pt}(2)-\mathrm{Pt}(3) 2.656(5) \AA, \mathrm{Pt}(1)-\mathrm{Hg}-\mathrm{Pt}(2) 53.0(1)$, $\mathrm{Pt}(1)-\mathrm{Hg}-\mathrm{Pt}(3) 54.2(1), \mathrm{Pt}(2)-\mathrm{Hg}-\mathrm{Pt}(3) 53.8(1), \mathrm{Hg}-\mathrm{Pt}(1)-\mathrm{Pt}(2) 63.8(1), \mathrm{Hg}-\mathrm{Pt}(1)-\mathrm{Pt}(3) 61.0(1), \mathrm{Hg}-$ $\mathrm{Pt}(2)-\mathrm{Pt}(1) 63.3(1), \mathrm{Hg}-\mathrm{Pt}(2)-\mathrm{Pt}(3) 60.9(1), \mathrm{Hg}-\mathrm{Pt}(3)-\mathrm{Pt}(1) 64.8(2), \mathrm{Hg}-\mathrm{Pt}(3)-\mathrm{Pt}(2) 65.3(2), \mathrm{Pt}(2)-$ $\mathrm{Pt}(1)-\mathrm{Pt}(3) 59.7(1), \mathrm{Pt}(1)-\mathrm{Pt}(2)-\mathrm{Pt}(3) 60.3(1), \mathrm{Pt}(1)-\mathrm{Pt}(3)-\mathrm{Pt}(2) 60.0(1)^{\circ}$.
core to give $\mathrm{Pt}_{3}\left(2,6-\mathrm{Me}_{2} \mathrm{C}_{6} \mathrm{H}_{3} \mathrm{NC}\right)_{6}$ [3]. The unusual stability of cluster 3 is probably responsible for a cage effect.

The IR spectrum of cluster 2 indicated the presence of both bridging and terminal isocyanide groups ( $\left.\nu(\mathrm{N} \equiv \mathrm{C}) c a .2100,1920, \nu(\mathrm{C}=\mathrm{N}) c a .1700,1660 \mathrm{~cm}^{-1}\right)$. The electronic absorption spectrum ( $\lambda_{\max } c a .670 \mathrm{~nm}$ ) was similar to that of 3 . Further, cluster 2 reacted smoothly with diphosphines to yield the close-type cluster 3. From these, cluster 2 was assumed to have an incomplete cage structure (called "open-type") in which a $\mathrm{Hg}_{2}$ unit was incorporated (Scheme 1).

When dppb $(n=4)$ was used, the green complex formulated as $\left[\mathrm{HgPt}_{6}(\mathrm{dppb})_{2^{-}}\right.$ $\left.(\mathrm{RNC})_{8}\right] \cdot \mathrm{C}_{6} \mathrm{H}_{6}\left(\mathbf{4 a}, \mathrm{R}=2,6-\mathrm{Me}_{2} \mathrm{C}_{6} \mathrm{H}_{3} 62 \% ; \mathbf{4 b}, \mathrm{R}=2,4,6-\mathrm{Me}_{3} \mathrm{C}_{6} \mathrm{H}_{2} 30 \%\right.$ ) was obtained as the only product [13*]. The analytical and spectral data suggested that the cluster 4 had an open-type cage structure where a single mercury atom was sandwiched between the two $\mathrm{Pt}_{3}$ triangles (Scheme 1). Unlike cluster 2, the single

Fig. 2. Molecular orbitals of the $\mathrm{Pt}_{3}$ triangular unit.

Scheme 1.
mercury cluster 4 could not be converted to a close-type one when treated with dppb, presumably because the steric repulsions of phenyl rings between the two $\mathrm{Pt}_{3}$ triangles increased with dppb which has a relatively short methylene chain $(n=4)$. Employing dppe $(n=2)$ and $\operatorname{dppp}(n=3)$, no $\mathrm{Hg}-\mathrm{Pt}$ mixed metal cluster was obtained. Thus, the number of methylene groups of the diphosphines plays an important factor in the formation of the mixed-metal clusters.

9 The crystals of $\mathbf{3 b}$ were extremely unstable in air, so a crystal sealed into a glass tube capillary with a small droplet of the mother liquid was used to collect diffraction data. Even under such condition, intensities of the standard reflections exhibited a time-dependent decrease, and two crystals were used to obtain diffraction data of $2 \theta<45^{\circ}$ on a Rigaku AFC4 four-circle automated diffractometcr. The unit cell dimensions were determined with 20 reflections in the range of $20<2 \theta<30^{\circ}$ for each crystal, and the arithmetic mean was used as the unit cell dimensions in the subsequent structure solution. Crystal data: $\mathrm{C}_{142} \mathrm{H}_{145} \mathrm{~N}_{6} \mathrm{Hg}_{2} \mathrm{Pt}_{6} \mathrm{P}_{6} \cdot 2 \mathrm{C}_{6} \mathrm{H}_{6}, M=3878.6$, monoclinic, space group $\mathrm{C} 2 / \mathrm{c}$, $a=56.86(8), b=15.120(8), c=31.01(3) \AA, \beta=141.29(6)^{\circ}, V=16673 \AA^{3}, Z=4, D_{\mathrm{c}}=1.546 \mathrm{~g} \mathrm{~cm}^{-3}$, Mo- $K_{\alpha}$ radiation. The structure was solved by direct methods (multan 78) and refined by block-diagonal least squares techniques to $R=0.104, R_{w}=0.085$ using 4990 unique reflections with $F_{\mathrm{o}}>3 \sigma\left(F_{\mathrm{o}}\right)(\mathrm{Hg}, \mathrm{Pt}$ and P atoms were refined with anisotropic thermal parameters and the others with isotropic parameters). All calculations were carried out on a FACOM M-780 computer with the program system Unics III (T. Sakurai and K. Kobayashi, Rikagaku Kenkyusho Hokoku, 55 (1979) 69).
