# Crystal structure of $\mathrm{Fe}\left(\eta^{6}-\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{BCMe}_{3}\right)_{2}$, a "problem structure" 

Melvyn Rowen Churchill and Ronald F. See<br>Department of Chemistry, State University of New York at Buffalo, Buffalo, NY 14214 (USA)

(Received June 16, 1992; in revised form October 5, 1992)

#### Abstract

The complex $\mathrm{Fe}\left(\eta^{6}-\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{BCMe}_{3}\right)_{2}$ crystallizes in the centrosymmetric triclinic space group $P \overline{1}\left(C_{\mathrm{i}}{ }^{1}\right.$; No. 2) with unit cell dimensions of $a 8.770(1) \AA, b 8.878(1) \AA, c 11.991(1) \AA, \alpha 107.56(1)^{\circ}, \beta 90.85(1)^{\circ}, \gamma 90.13(1)^{\circ}, V 890.0(2) \AA^{3}$ and $Z=2$. A full sphere of data was collected on a four-circle diffractometer. The structure was solved and refined to $R \quad 7.93 \%$ for all 3155 independent reflections and $R 4.98 \%$ for those 2002 data with $\left|F_{0}\right|>6 \sigma\left|F_{0}\right|$. The molecules lie on crystallographic inversion centers at $0,0,0$ and $1 / 2,0,1 / 2$; the crystallographic asymmetric unit therefore consists of two independent half molecules. The molecule centered at $0,0,0$ (molecule " $A$ ") is ordered and well-defined; that centered on $1 / 2,0,1 / 2$ (molecule " $B$ ") is probably disordered, as indicated by larger "thermal parameters" and a greater range of apparent interatomic distances. Discussion emphasizes the geometry of molecule $A$, which has precise $C_{i}$ symmetry with $\operatorname{Fc}(1 \mathrm{~A})-\mathrm{B}(1 \mathrm{~A}) 2.297(4) \AA$ and $\mathrm{Fe}(1 \mathrm{~A})-\mathrm{C}($ ring $)$ distances ranging from $2.057(6) \AA$ to $2.138(4) \AA$.

## 1. Introduction

Complexes of the formal $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{BR}^{-}$anion were reported by Herberich and Greiss in 1972 [1]. Thus, the cobalt complexes $\mathrm{Co}\left(\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{BR}\right)_{2}$ and $\mathrm{Co}\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)$ ( $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{BR}$ ) were formed by ring expansion of the $\mathrm{C}_{5} \mathrm{H}_{5}$ rings in $\mathrm{Co}\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)_{2}$ by use of the organoboron dihalides $\mathrm{RBX}_{2}\left(\mathrm{R}=\mathrm{C}_{6} \mathrm{H}_{5}, \mathrm{X}=\mathrm{Cl}, \mathrm{Br} ; \mathrm{R}=\mathrm{CH}_{3}, \mathrm{X}=\right.$ $\mathrm{Br})$. This and the later extensive work of Herberich and his coworkers have been summarized in a review article [2].

A second entry into this field was made when Ashe and coworkers utilized the techniques developed in their previous synthesis of the " 1 -phenylborabenzene" anion $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{BPh}^{-}$[3] to prepare a variety of bis(1-sub-stituted-"borabenzene") iron complexes [4], including the complex $\mathrm{Fe}\left(\eta^{6}-\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{BCMe}_{3}\right)_{2}$ used in the current study.

It should be noted that the nomenclature for compounds based on $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~B}$ and the $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{BH}^{-}$ion has undergone some changes [2]. Thus, the unknown parent compound $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~B}$ has been termed borabenzene, borinane, borinine and borine. The $\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{BH}^{-}$anion is

[^0]now known as boratabenzene, but was originally termed borinate [1] or the borabenzene anion [3,4].

## 2. Experimental details

Crystals of $\mathrm{Fe}\left(\eta^{6}-\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{BCMe}_{3}\right)_{2}$ were provided to M.R.C. by Professor A.J. Ashe, III in 1974. Attempts to solve the structure at that time were fruitless because of the mistaken assumption that the crystal was monoclinic. (Interaxial angles are, in fact, $107.56^{\circ}$, $90.85^{\circ}$ and $90.13^{\circ}$, see below). The remaining crystals were stored, mislaid for about 17 years and were rediscovered recently. No visible decomposition had occurred and a second crystallographic study was undertaken. The composition of the material was also checked by ${ }^{1} \mathrm{H}$ NMR (in $\mathrm{CDCl}_{3}$ ); the pattern described for the complex in ref. 4 was observed.

The following structural study gives rise to some obvious problems. We emphasize that complete structural analyses (with a full sphere of diffraction data) were performed on two different crystals, yielding equivalent results. We provide details of the better such study (in terms of slightiy lower $R$-factors).

A red crystal of approximate dimensions $0.4 \times 0.3 \times$ 0.3 mm was sealed into a thin-walled capillary and was aligned on an upgraded Syntex P2 ${ }_{1}$ /Siemens R3
diffractometer. A complete shell of data ( $\pm h, \pm k, \pm l$ ) was collected for the range $2 \theta=5.0-50.0^{\circ}$. Details of data collection and refinement are provided in Table 1.

| Largest difference peak | $0.67 \mathrm{e} \AA^{-3}$ |
| Largest difference hole | $-0.50 \mathrm{e}^{\circ}{ }^{-3}$ |

The crystal belongs to the triclinic system, but the angles $\beta$ and $\gamma$ are close to $90^{\circ}$, with $\beta=90.85(1)^{\circ}$ and $\gamma=90.13(1)^{\circ}$. A further observation is that data with $h+l=2 n+1$ are systematically weak - i.e., the unit cell is pseudo-B-centered. Possible space groups are the non-centrosymmetric triclinic space group P1 (No. 1) or the centrosymmetric triclinic space group $P \overline{1}$ (No. 2). We chose the latter on the basis of (a) statistical distribution of $E$-values [5], (b) the far greater probability of a synthetic triclinic crystal with $Z=2$ belonging to the centrosymmetric space group $P \overline{1}$, rather than to the noncentrosymmetric space group $P 1$ [6] and (c) the extraordinarily small probability of a centrosymmetric molecule crystallizing in the two different chiral forms of a enantiometrically pure non-centrosymmetric crystal ( D - and l-hands of the polar space group P1) [7]. The 6310 data were merged to 3155 independent reflections, with the excellent merging factor of $R_{\text {int }}=0.94 \%$.

The structure was solved by direct methods using the Siemens shelx plus system. The appearance of iron atoms at $0,0,0$ and $1 / 2,0,1 / 2$ explained the pseudo-B-centering condition. Refinement converged with $R 7.93 \%$ and $w R 7.56 \%$ for all 3155 unique data and $R 4.98 \%$ and $w R 5.51 \%$ for those 2002 data with $\left|F_{0}\right|>6 \sigma\left|F_{0}\right|$. Hydrogen atoms were placed in calculated positions with $d(\mathrm{C}-\mathrm{H})=0.96 \AA$ [8]. Residual features on a final difference-Fourier map were in the range $-0.50 \rightarrow+0.67 \mathrm{e}^{-} \AA^{-3}$. The structure thus appeared to be both correct and complete. However, there are some indications of a disorder problem (see Discussion).

Final atomic coordinates are collected in Table 2. Anisotropic displacement coefficients are provided in Table 3.

## 3. Discussion

The crystallographic asymmetric unit is composed of two independent half-molecules. Molecule " $A$ " is centered on $\mathrm{Fe}(1 \mathrm{~A})$ at the inversion center at $0,0,0$; molecule " B " is centered on $\mathrm{Fe}(1 \mathrm{~B})$ at the inversion center at $1 / 2,0,1 / 2$. Packing of the molecules in the unit cell is illustrated in Figs. 1 and 2. Interatomic distances and angles are collected in Tables 4 and 5.

As shown in Fig. 3, molecule A is well-behaved, with normal looking atomic vibration ellipsoids and with normal and internally consistent bond lengths (vide infra). In contrast to this, molecule B has inappropriately shaped "vibration ellipsoids" (see Fig. 4), which clearly indicate some effect other than true vibration; bond lengths involving the $\eta^{6}-\mathrm{C}_{5} \mathrm{~B}$ ring are also systematically in error.

We will continue by discussing, in order, the dimensions within the ordered molecule $A$ and the nature of the disorder in molecule $B$.

[^1]
### 3.1. Molecule $A$

This molecule is ordered and has precise $C_{i}$ symmetry - the atoms in the $\eta^{6}-\mathrm{C}_{5} \mathrm{~B}$ ring are therefore eclipsed although the two $\mathrm{B}-\mathrm{CMe}_{3}$ moieties are in a relative trans-( $1,4^{\prime}$ ) juxtaposition (see Fig. 5).

Distances from the iron atom to the $\eta^{6}$-ligand show the following trends. The $\mathrm{Fe}(1 \mathrm{~A})-\mathrm{B}(1 \mathrm{~A})$ distance of $2.297(4) \AA$ is the longest; those carbon atoms adjacent to boron are associated with the next longest distances, with $\mathrm{Fe}(1 \mathrm{~A})-\mathrm{C}(2 \mathrm{~A})=2.138(4) \AA$ and $\mathrm{Fe}(1 \mathrm{~A})-$ $\mathrm{C}(6 \mathrm{~A})=2.128(5) \AA$; the remaining three distances are the shortest with values of, cyclically, $\mathrm{Fe}(1 \mathrm{~A})-\mathrm{C}(3 \mathrm{~A})=$ $2.081(4) \AA, \mathrm{Fe}(1 \mathrm{~A})-\mathrm{C}(4 \mathrm{~A})=2.078(5) \AA$ and $\mathrm{Fe}(1 \mathrm{~A})-$ $\mathrm{C}(5 \mathrm{~A})=2.057(6)$. Distances within the $\eta^{6}-\mathrm{C}_{5} \mathrm{~B}$ ring include the boron-carbon distances of $\mathrm{B}(1 \mathrm{~A})-\mathrm{C}(2 \mathrm{~A})=$ $1.523(6) \AA$ and $\mathrm{B}(1 \mathrm{~A})-\mathrm{C}(6 \mathrm{~A})=1.501(7) \AA$ (average $\mathrm{B}-\mathrm{C}=1.512 \AA$ ) and carbon-carbon distances of $\mathrm{C}(2 \mathrm{~A})-\mathrm{C}(3 \mathrm{~A})=1.399(8) \AA, \mathrm{C}(3 \mathrm{~A})-\mathrm{C}(4 \mathrm{~A})=1.388(9) \AA$, $\mathrm{C}(4 \mathrm{~A})-\mathrm{C}(5 \mathrm{~A})=1.383(9) \quad \AA$ and $\mathrm{C}(5 \mathrm{~A})-\mathrm{C}(6 \mathrm{~A})=$ 1.417(8) $\AA$ (average $\mathrm{C}-\mathrm{C}=1.397 \AA$ ).

The exocyclic boron-(tertiary butyl) distance, $\mathrm{B}(1 \mathrm{~A})-\mathrm{C}(11 \mathrm{~A})=1.609(7) \AA$, is some $0.10 \AA$ longer than the intraring $\mathrm{B}-\mathrm{C}$ distances, confirming the multiple bond character of the latter.

Angles within the $\eta^{6}-\mathrm{C}_{5} \mathrm{~B}$ ring are essentially regular except for a contraction at boron associated with the longer $\mathrm{B}-\mathrm{C}$ bonds. Thus, the angle $\mathrm{C}(6 \mathrm{~A})-\mathrm{B}(1 \mathrm{~A})-$ $\mathrm{C}(2 \mathrm{~A})$ is $111.3(4)^{\circ}$; angles ortho to this are $\mathrm{B}(1 \mathrm{~A})-$ $\mathrm{C}(2 \mathrm{~A})-\mathrm{C}(3 \mathrm{~A}) \quad 122.3(4)^{\circ}$ and $\mathrm{B}(1 \mathrm{~A})-\mathrm{C}(6 \mathrm{~A})-\mathrm{C}(5 \mathrm{~A})$ $122.5(4)^{\circ}$ (average $=122.4^{\circ}$ ); angles at the meta position are $\mathrm{C}(2 \mathrm{~A})-\mathrm{C}(3 \mathrm{~A})-\mathrm{C}(4 \mathrm{~A}) 121.4(5)^{\circ}$ and $\mathrm{C}(6 \mathrm{~A})-$ $\mathrm{C}(5 \mathrm{~A})-\mathrm{C}(4 \mathrm{~A}) 121.1(5)^{\circ}$ (average $=121.3(5)^{\circ}$; the angle at the para position is $\mathrm{C}(3 \mathrm{~A})-\mathrm{C}(4 \mathrm{~A})-\mathrm{C}(5 \mathrm{~A}) 120.8(6)^{\circ}$.

Although, to the best of our knowledge, no bis(boratabenzene)iron complexes have been studied, similar patterns of $\mathrm{M}-\mathrm{C}(\mathrm{B})$ distances and intraring angles have been observed in such species as $c i s-\left[\left(\eta^{6}\right.\right.$ $\left.\left.\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{BMe}\right) \mathrm{Fe}(\mathrm{CO})(\mu-\mathrm{CO})\right]_{2} \quad[9], \mathrm{Co}\left(\eta^{6}-\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{BMe}\right)_{2}$ [10], $\mathrm{Co}\left(\eta^{6}-\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{BOMe}\right)_{2} \quad[2,10], \quad\left(\eta^{6}-\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{BPh}\right) \mathrm{Co}$ $(\mathrm{CO})_{2}$ [11], $\left(\eta^{6}-\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{BPh}\right) \mathrm{Mn}(\mathrm{CO})_{3}$ [9] and ( $\eta^{6}$ $\left.\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{BMe}\right) \mathrm{V}(\mathrm{CO})_{4}$ [12].

### 3.2. Molecule B

This molecule is associated with anomalous vibration ellipsoids (specifically those for atoms C(2B), $C(3 B), C(5 B)$ and $C(6 B)$ and, possibly, C(4B)-see Fig. 4). Note that the iron atom, $\mathrm{Fe}(1 \mathrm{~B})$, and the $\mathrm{B}-\mathrm{CMe}_{3}$ moiety show no unusual effects. As may be seen in Table 3, the largest $U_{i i}$ values for atoms $\mathrm{C}(2 \mathrm{~B}) \rightarrow \mathrm{C}(6 \mathrm{~B})$ are far greater (by a factor of $\times 3.1$ to $\times 5.7$ ) than for atoms $C(2 A) \rightarrow C(6 A)$; no such differences are found for other atoms. Possible explanations include the following.

Fig. 1. Packing of molecules viewed down $b$ and showing the pseudoB -centering.
(1) Crystal twinning. This would be unusual for such a low crystal class as triclinic, but not impossible since $a$ and $b$ are approximately equal and $\gamma$ is close to $90^{\circ}$. We did, however, carry out complete structural analyses on two different well-formed crystals.

Fig. 2. Packing of molecules viewed down $a$.
(2) Misidentification of crystal class and/or space group. The misidentification of crystal class is now unlikely, since we had previously misidentified this complex as belonging to the higher monoclinic system - see Experimental details. Misidentification of the space group in the triclinic system is unlikely. That molecule situated at the inversion center at $0,0,0$ (molecule A) is well behaved and clearly has true $C_{i}$ symmetry. That centered at $1 / 2,0,1 / 2$ (molecule $\mathbf{B}$ ) is less well behaved. It is extraordinarily unlikely that the

| $\mathrm{C}(11 \mathrm{~A})-\mathrm{C}(14 \mathrm{~A})$ | $1.477(8)$ | $\mathrm{C}(11 \mathrm{~B})-\mathrm{C}(14 \mathrm{~B})$ | $1.531(7)$ |

true space group is $P 1$ with only minor deviations from $P \overline{1}$. (At the suggestion of a referee we have carried out refinement in space group $P 1$. The results were unsatisfactory. Bond distances in molecule $B$ became even worse, bond distances in molecule A deteriorated badly and " $\eta$-refinement" produced a value of $\eta=+0.04(6)$. Clearly P1 is not the correct space group.)
(3) An artifact of crystal decomposition. Frankly, we are not too familiar with this problem (nor, we suspect, is anyone else). However, the classic example is that of $\left[\mathrm{IrO}_{2}\left(\mathrm{Ph}_{2} \mathrm{PCH}_{2} \mathrm{PPh}_{2}\right)_{2}\right]\left[\mathrm{PF}_{6}\right]$ originally studied by

Fig. 3. Labeling of atoms and atomic vibration ellipsoids for the ordered molecule A.

McGinnety et al. [13] and reexamined by Laing et al. [14]. Here it was established that crystal decomposition had led to mutually inconsistent Ir -ligand distances and an anomalously long $\mathrm{O}-\mathrm{O}$ bond. This seems not be relevant to the present case, since the crystals appeared to be of excellent quality (despite their age) and only one site is affected.
(4) Co-crystallization of two different molecular species. This seems improbable since (i) the complex is well characterized, (ii) only one site is affected and (iii) the overall shape of molecule B is essentially the same as that of molecule A. The only chemically accessible

TABLE 5. Interatomic angle (deg)

| Molecule A (ordered) |  | Molecule B (disordered) |  |
| :---: | :---: | :---: | :---: |

| $\mathrm{C}(6 \mathrm{~A})-\mathrm{B}(1 \mathrm{~A})-\mathrm{C}(11 \mathrm{~A})$ | 125.0(4) | $\mathrm{C}(6 \mathrm{~B})-\mathrm{B}(1 \mathrm{~B})-\mathrm{C}(11 \mathrm{~B})$ | $125.8(5)$ |
| $\mathrm{B}(1 \mathrm{~A})-\mathrm{C}(11 \mathrm{~A})-\mathrm{C}(12 \mathrm{~A})$ | 112.2(4) | $\mathrm{B}(1 \mathrm{~B})-\mathrm{C}(11 \mathrm{~B})-\mathrm{C}(12 \mathrm{~B})$ | 107.7(5) |
| $B(1 A)-C(11 A)-O(13 A)$ | 106.2(5) | $\mathrm{B}(1 \mathrm{~B})-\mathrm{C}(11 \mathrm{~B})-\mathrm{C}(13 \mathrm{~B})$ | $113.7(4)$ |
| $\mathrm{B}(1 \mathrm{~A})-\mathrm{C}(11 \mathrm{~A})-\mathrm{C}(14 \mathrm{~A})$ | 112.5(4) | $\mathrm{B}(1 \mathrm{~B})-\mathrm{C}(11 \mathrm{~B})-\mathrm{C}(14 \mathrm{~B})$ | 112.9(4) |
| $\mathrm{C}(12 \mathrm{~A})-\mathrm{C}(11 \mathrm{~A})-\mathrm{C}(13 \mathrm{~A})$ | 108.6(5) | $\mathrm{C}(12 \mathrm{~B})-\mathrm{C}(11 \mathrm{~B})-\mathrm{C}(13 \mathrm{~B})$ | $109.9(5)$ |
| $\mathrm{C}(12 \mathrm{~A})-\mathrm{C}(11 \mathrm{~A})-\mathrm{C}(14 \mathrm{~A})$ | 108.2(5) | $\mathrm{C}(12 \mathrm{~B})-\mathrm{C}(11 \mathrm{~B})-\mathrm{C}(14 \mathrm{~B})$ | 105.5(4) |
| $\mathrm{C}(13 \mathrm{~A})-\mathrm{C}(11 \mathrm{~A})-\mathrm{C}(15 \mathrm{~A})$ | 109.1(5) | $\mathrm{C}(13 \mathrm{~B})-\mathrm{C}(11 \mathrm{~B})-\mathrm{C}(15 \mathrm{~B})$ | 106.8(1) |

Fig. 4. Labeling of atoms and "atomic vibration ellipsoids" for the disordered molecule B .

Fig. 5. The eclipsed configuration of molecule A.
species would appear to be $\mathrm{Fe}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{BCMe}_{3}\right)\left(\eta^{5}-\right.$ $\mathrm{C}_{5} \mathrm{H}_{5}$ ), but this would leave large voids in the crystal (there is also no ${ }^{1} \mathrm{H}$ NMR evidence for this species see Experimental details).
(5) Disorder of molecules at site B. There could be two (or more) sites of equivalent energy for molecule $B$. The location of the iron atom is secure at $1 / 2,0$, $1 / 2$ and the peripheral $\mathrm{B}-\mathrm{CMe}_{3}$ groups appear to be firmly locked into position with B-C and C-Me distances in good agreement with those of molecule A . The proposed disorder would involve either a static or (less likely) dynamic rotation of $\mathrm{C}_{5} \mathrm{~B}$ moieties about the $\mathrm{B}-\mathrm{CMe}_{3}$ bond with concomitant slippage on the surface of the iron atom. The observed $\mathrm{Fe}(1 \mathrm{~B})-\mathrm{C}(n \mathrm{~B})$
distances, which are shorter than the $\mathrm{Fe}(1 \mathrm{~A})-\mathrm{C}(\mathrm{NB})$ distances by $0.034 \AA(n=2), 0.086 \AA(n=3), 0.110 \AA$ ( $n=4$ ), $0.058 \AA(n=5)$ and $0.037 \AA(n=6)$ are then the artificial results of averaging two or more sets of atomic locations. This similarly explains the anomalous range of C -C(ring) "distances" ( $1.224-1.566 \AA$ ) in molecule B .
(6) Existence of a possible superlattice. This was checked on photographs; no evidence for such a superlattice was found.

Overall, we prefer explanation (5), although (1) is not impossible. In either case there are two or more orientations for molecule $B$ at the defined site.

## Acknowledgments

We thank Professor A.J. Ashe, III for providing the sample and Professor Ivan Bernal for helpful comments. Upgrade of the diffractometer was made possible by Grant 89-13733 from the Chemical Instrumentation Program of the National Science Foundation.
