#### Abstract

The dynamic stereochemistry of two substitution reactions [(i) and (ii)] for the thiocyanate and isocyanate complexes of titanocene has been reinvestigated. $$
\begin{equation*} \left[\left(\eta^{5}-\mathrm{Cp}\right)\left(\eta^{5}-\mathrm{Cp}^{\prime}\right) \mathrm{TiOArX}\right] \xrightarrow[\mathrm{I}]{\mathrm{Br}^{-}}\left[\left(\eta^{5}-\mathrm{Cp}\right)\left(\eta^{5}-\mathrm{Cp}^{\prime}\right) \mathrm{TiBrX}\right] \xrightarrow[\mathrm{ii}]{\mathrm{SC}_{6} \mathrm{H}_{5}^{-}}\left[\left(\eta^{5}-\mathrm{Cp}\right)\left(\eta^{5}-\mathrm{Cp}^{\prime}\right) \mathrm{Ti}\left(\mathrm{SC}_{6} \mathrm{H}_{5}\right) \mathrm{X}\right] \tag{1} \end{equation*}
$$ $\left(\mathrm{Cp}=\mathrm{C}_{5} \mathrm{H}_{5} ; \mathrm{Cp}^{\prime}=1-\mathrm{Me}-2-\mathrm{PrC}_{5} \mathrm{H}_{3} ; \mathrm{Ar}=2,6-\mathrm{Me}_{2} \mathrm{C}_{6} \mathrm{H}_{3} ; \mathrm{X}=\mathrm{NCO}, \mathrm{NCS}\right.$ or Cl$)$ The metathesis reaction (ii) has been shown to be chemoselective and stereospecific with inversion of the configuration at the titanium for $\mathrm{X}=$ NCO and retention for $\mathrm{X}=$ NCS. This stereochemical behaviour contrasts with that proposed previously, i.e. inversion of configurations for both $\mathrm{X}=$ NCO and $\mathrm{X}=$ NCS. The present result is unambiguously supported by the crystallographic structure of the racemic compound $1 \mathbf{c}^{\prime}\left(\mathrm{X}=\mathrm{Cl}, \mathrm{m} . \mathrm{p} .186^{\circ} \mathrm{C}\right.$ ), which was chosen as the starting stereochemical reference. The complex $1 \mathbf{l c}^{\prime}$ crystallizes in the monoclinic system, space group $C_{c}$. Two well-characterized quasi-eclipsed and staggered conformational forms of the complex $\mathbf{1 c}^{\prime}$ are presented. According to Seebach's nomenclature, this structure corresponds to the $\mathbf{u}(\mathrm{Ti}, \mathrm{p})$ configuration.

Keywords: Titanium; Titanocene; Chirality; X-ray diffraction

## 1. Introduction

Our previous work [1] dealt with the dynamic stereochemistry of the two new substitution reactions (i) and (ii) in Scheme 1. These reactions started from pairs of racemic diastereomeric pseudohalogen titanocene complexes 1 ( $\mathrm{X}=\mathrm{NCO}$ or NCS), which have both a central chirality at the metal atom and a pianar chiral-

[^0]ity at the substituted cyclopentadienyl ring. The stereochemical course of the reactions was unequivocally established on the basis of the X-ray of structures 1b (m.p. $193^{\circ} \mathrm{C}$ ) and $\mathbf{3 b ^ { \prime }}$ (m.p. $173^{\circ} \mathrm{C}$ ) (see Fig. 1; only one of two enantiomers is presented here), and ${ }^{1} \mathrm{H}$ NMR ( $\mathrm{X}=\mathrm{NCS}$ or NCO ) [2] and photoelectron spectral data [1]. It was rationalised by extended Hückel calculations [1]. Reaction (i) is shown to occur with retention of the configuration at the titanium atom for $\mathrm{X}=\mathrm{NCS}$ as well as for $\mathrm{X}=\mathrm{NCO}$. In contrast, the stereochemical course of reaction (ii) depends on the heteroatom used, giving

Scheme 1.
retention for $X=$ NCS and inversion of the configuration for $\mathrm{X}=\mathrm{NCO}$.

However, retention of configuration in (ii), $\mathrm{X}=\mathrm{NCS}$, appears to contrast with the inversion previously proposed for this reaction $[2 b, 3]$. This is worth noting as it is based on the chemical relation between compounds 1,2 and 3 using the racemic diastereomeric precursors ( $\mathrm{X}=\mathrm{Cl}$ ), 1c (m.p. $181^{\circ} \mathrm{C}$ ) and $1 \mathrm{c}^{\prime}$ (m.p. $186^{\circ} \mathrm{C}$ ) (Scheme 2). The diastereomers $\mathbf{1 c}$ and $\mathbf{1 c}{ }^{\prime}$ have been especially considered as stereochemical references. Their configurational assignments were based on the close analngy between their ${ }^{1} \mathrm{H}$ NMR data and those of the racemic compound $4 \mathbf{c}$, which is representative of the 1-3 series $\left(\mathrm{Cp}^{\prime \prime}=1-\mathrm{Me}-3-{ }^{\mathrm{i}} \mathrm{PrC}_{5} \mathrm{H}_{3}\right)$ for which the X-ray structure has already been established (Fig. 2; only one of two enantiomers is shown) $[4,5]$. Such internal consistency led us to propose structure $\mathrm{I}(\mathrm{X}=\mathrm{Cl}, \mathrm{Y}=\mathrm{OAr})$ for $\mathbf{1 c}$ and structure II for the diastereomeric complex $\mathbf{1 c}^{\prime}$ (Fig. 3; only one of two enantiomers is shown here). The NMR-based comparison of pairs of diastereomers which possess different planar chiralities (series 1-2 versus $1-3$ ) alone, thus appears to be inadequate.

## 2. Results and discussion

In order to resolve this contradiction we have determined the X-ray structure of one of the two diastereomers with m.p. $186^{\circ} \mathrm{C}\left(1 \mathrm{c}^{\prime}\right)$.

1 b (m.p. $193^{\circ} \mathrm{C}$ )

### 2.1. X-Ray analysis of compound $1 \boldsymbol{c}^{\prime}$

$\mathrm{C}_{22} \mathrm{H}_{27} \mathrm{ClOTi}: \mathrm{M}=390.82$, monoclinic, $C_{c}, \quad a=$ $16.291(6), b=15.702(5), c=15.719(4) \AA, \beta=92.43(5)^{\circ}$, $\mathrm{V}=4017(4) \AA^{-3}, Z=8, D_{\mathrm{x}}=1.292 \mathrm{mg} \mathrm{m}{ }^{-3}, \lambda(\mathrm{Mo}$ $\mathrm{K} \alpha)=0.70926 \AA, \mu=5.61 \mathrm{~cm}^{-1}, F(000)=1648, T=$ 293 K . The sample ( $0.22 \times 0.26 \times 0.32 \mathrm{~mm}$ ) was studied on an automatic Enraf-Nonius CAD4 diffractometer with graphite monochromatized Mo $\mathrm{K} \alpha$ radiation. The cell parameters were obtained by fitting a set of 25 high $-\theta$ reflections. Data collection: $2 \theta_{\max }=50^{\circ}$, scan $\omega / 2 \theta=1, t_{\text {max }}=60 \mathrm{~s}$, range $19 \leqslant h \leqslant 19,0 \leqslant k \leqslant 18$, $0 \leqslant l \leqslant 18$, intensity controls without appreciable decay $(0.4 \%)$ gave 3821 reflections of which 2732 were independent ( $R_{\mathrm{int}}=0.017$ ) with $I>\sigma(I)$.

After Lorentz and polarization corrections, the structure was solved by a Patterson map which indicated the position of the two Ti atoms in the structure. The remaining non-hydrogen atoms of the molecule were found after several scale factor and Fourier difference calculations. After isotropic ( $R=0.012$ ) and anisotropic refinement ( $R=0.063$ ), many hydrogen atoms were found Fourier difference analysis (between 0.43 and $0.19 \mathrm{e}^{\AA^{-3}}$ ). The whole structure was refined by a full-matrix least-squares techniques, use of $F$ magnitude; $x, y, z, \beta_{i j}$ for $\mathrm{Ti}, \mathrm{Cl}, \mathrm{C}$ and O atoms and $x, y, z$ fixed for H atoms; 450 variables and 2732 observations; $w=1 / \sigma\left(F_{\mathrm{o}}\right)^{2}=\left[\sigma^{2}(I)+\left(0.04 F_{\mathrm{o}}^{2}\right)^{2}\right]^{-1 / 2}$ with the resulting $R=0.048, R_{w}=0.039$ and $S_{w}-1.72$ (residual $\Delta \rho<0.22 \mathrm{e}^{\AA} \AA^{-3}$ ).

Atomic scattering factors were taken from International Tables for $X$-ray Crystallography [6a]. All the calculations were performed on a Digital MicroVAX 3100 computer using the molen package (Enraf-Nonius, [6b]).

& \mathbf{1}(\mathrm{X}: \mathrm{Cl}) \xrightarrow{\mathrm{NCS}^{-}} \mathbf{1}(\mathrm{X}: \mathrm{NCS}) \\
& \mathbf{1 c}\left(\mathrm{m} . \mathrm{p} .181^{\circ} \mathrm{C}\right) \longrightarrow \mathbf{1 b} 60 \%+\mathbf{1 b}^{\prime} 40 \% \\
& \mathbf{1 \mathbf { c } ^ { \prime }}\left(\mathrm{~m} . \mathrm{p} .186^{\circ} \mathrm{C}\right) \longrightarrow \mathbf{1 b} 40 \%+\mathbf{1 b}^{\prime} 60 \%
\end{aligned}
$$

$4 \mathrm{c}\left(\mathrm{m} . \mathrm{p} .150^{\circ} \mathrm{C}\right.$ )

$4 c^{\prime}\left(\right.$ m.p. $\left.122^{\circ} \mathrm{C}\right)$

Fig. 2. X-ray structures of 4 c and $4 \mathbf{c}^{\prime}$.

The racemic form of the compound crystallises with two conformations A and B (Figs. 4 and 5) [6c]. Table 1 lists the atomic coordinates, Tables 2 and 3 list the bond distances and bond angles, and Table 4 gives the least-square planes of the cyclopentadienyl rings, and the distances and angles of the various atoms on the basis of these planes. The whole structure, with its two conformations, is shown in Figs. 6 and 7 [6c].

The data show that the configuration and the two conformations are established unambiguously in the solid state. Structure I (Fig. 3) represents the complex $1 \mathrm{c}^{\prime}$, m.p. $186^{\circ} \mathrm{C}$. This structure may be defined by the relative configuration $\mathbf{u}(\mathrm{Ti}, \mathrm{p})[7,8]$. The results clearly reveal that the configuration previously established by NMR (structure II) is erroneous.

Table 5 provides comparative data for $\mathbf{1 c}{ }^{\prime}$ (m.p. $186^{\circ} \mathrm{C}$ ) and 4 c (m.p. $150^{\circ} \mathrm{C}$ ). The $\mathrm{Ti}-\mathrm{Cl}$ and $\mathrm{Ti}-\mathrm{O}$ distances, $\mathrm{Ti}-\mathrm{O}-\mathrm{C}$ and $\mathrm{Cl}-\mathrm{Ti}-\mathrm{O}$ angles are quite similar and the main differences concern the $\mathrm{Ti}-\mathrm{C}^{*}$ and $\mathrm{O}-\mathrm{C}$ distances and the relative positions of the cyclopentadienyl planes.

The views of the two molecules show that the cyclopentadienyl rings are eclipsed in one case and staggered in the other. In these two conformations, the Cl atom (which is smaller than $-\mathrm{OC}_{6} \mathrm{H}_{3} \mathrm{Me}_{2}$ ) lies in the more congested part of the molecule.

The X-ray analysis demonstrates that $\mathbf{1 c} \mathbf{c}^{\prime}$ has the same configuration as its positional isomer $4 \mathbf{c}$. This is not expected from the spectral comparison of the latter and complex $1 \mathbf{c}$, a diastereomer of $1 \mathbf{c}^{\prime}$.

The methyl and isopropyl groups on the cyclopentadienyl ring were used as NMR probes. The resonances are shifted downfield or upfield according to the position of aryloxy group. As a result, it is possible to establish the relative configurations of the various pairs

$\overline{\text { Anisotropically refined atoms are given in the form of the isotropic equivalent thermal parameter defined as } B_{\mathrm{eq}}=4 / 3\left[a^{2} B_{1,1}+b^{2} B_{2,2}+c^{2} B_{3,3}\right.}$
$\left.+a b\left(\cos \gamma^{2}\right) B_{1,2}+a c(\cos \beta) B_{1,3}+b c(\cos \alpha) B_{2,3}\right]$.
of diastereomers, with the chlorine atom appearing to be located in the region between the two alkyl substituents of the cyclopentadienyl ring (Figs. 2 and 3).

However, the methyl proton resonances may be overlap the resonances of the 2,6 -methyl substituents of the aryloxy. This gave a problem previously with $\mathbf{4 c}$, for which the ${ }^{1} \mathrm{H}$ NMR spectrum was recorded in $\mathrm{CDCl}_{3}$ at 60 MHz [4]. Is this also responsible for the erroneous configurational assignments made for $1 \mathbf{c}^{\prime}$ ? In order to resolve this, we undertook a comparative ${ }^{1} \mathrm{H}$ NMR analysis using a 400 MHz instrument with two more suitable solvents, $\mathrm{C}_{6} \mathrm{D}_{6}$ and $\mathrm{C}_{6} \mathrm{D}_{5} \mathrm{CD}_{3}$. The ${ }^{1} \mathrm{H}$ NMR data obtained for two pairs of diastereomeric chloro-2,6-dimethylphenoxy titanocenes $1 \mathbf{c}, \mathbf{c}^{\prime}$ and $\mathbf{4 c}, \mathbf{c}^{\prime}$, possessing planar chiralities $1-2$ and $1-3$ are given in Table 6. Consistent with our previous observations, the methyl resonances are shielded and the isopropyl resonances are deshielded for the same diastereomer of each pair. These results led us at first to propose identical chiralities for $1 \mathbf{c}$ and 4 c .

The present study provides further information. The split in the two well-defined singlets relative to the diastereotopic aryloxy methyl groups contrasts with the single resonance observed in $\mathrm{CDCl}_{3}$. Temperaturevariation experiments provide a further insight into the relative characteristics of the two series. Temperature changes had almost the same effect on each of the two

[^1]diastereomers within a series. However, significant differences were observed between series. Coalescence takes place at $325 \mathrm{~K}\left(\mathrm{C}_{6} \mathrm{D}_{6}\right)$ for the pair of diastereomers of the $1-3$ series, but at $353 \mathrm{~K}\left(\mathrm{C}_{6} \mathrm{D}_{5} \mathrm{CD}_{3}\right)$ for that of the 1-2 series. Thus the rotational barrier appears to be greater for the latter than for the former. The diastereotopy of the methyls of the isopropyl groups is much more marked for one of the two diastereomers within either series (1c for the 1-2 and $\mathbf{4} \mathbf{c}^{\prime}$ for the $1-3$ series). The chemical shifts assignable to protons of the cyclopentadienyl ring tend to confirm correspondence between $1 \mathbf{c}$ and $\mathbf{4 c}$ '. Identical chiralities for $\mathbf{1 c}$ and $\mathbf{4 c} \mathbf{c}^{\prime}$ and for $\mathbf{1 c} \mathbf{c}^{\prime}$ and $\mathbf{4 c}$ would be still inferred.

Hence, according to the type of the NMR analysis used, opposite configurational assignments have been reached. It is therefore unjustified to use NMR data for inferring, for example, the position of a nucleus with respect to the region of diamagnetic anisotropy of the aryloxy fragment.

In order to explain these contradictory conclusions, we first identified marker groups with respect to the centre of gravity and the plane of the phenyl ring. The markers chosen were the methyl groups of $\mathbf{1 c}^{\prime}$ and of its constitutional isomer $\mathbf{4 c}$, for which crystallographic data are available. The distances are given in Table 5 and the coordinates of protons concerned are reported in the diagram which represents the model of benzene [9] (Fig. 8). We were thus able to examine the influence of the aromatic system on the chemical shift variations.

The methyl groups of $1 \mathbf{c}^{\prime}$ and 4 c appear to be located in the same deshielded region. However, the protons concerned are very near the boundary between this region and the shielding region. We assume that the methyl protons, whose coordinates in the diagram are relative to the crystallographic conformations of $\mathbf{1} \mathbf{c}^{\prime}$

Fig. 8. The diagnostic methyl groups of complexes $1 \mathbf{c}^{\prime}$ and $\mathbf{4 c}$ in the shielding-deshielding regions around a benzene ring. $\square$, Complex $1 \mathbf{c}^{\prime}$ (m.p. $186^{\circ} \mathrm{C}$ ); complex 4c (m.p. $150^{\circ} \mathrm{C}[5]$ ).
chiralities. Such a hypothesis is all the more plausible because of the easy rotation of the aryloxy group (temperature-variation experiments) as well as the different conformational features for $\mathbf{1 c}^{\prime}$ (Figs. 4 and 5) even in the solid state.

## 3. Experimental details

All manipulations of air-sensitive products were under purified argon using Schlenk techniques. Solvents were distilled under argon from sodium benzophenone immediately before use. Preparative thin-layer chromatography used silica gel 7732 G Merck ( 0.5 mm diameter) and silica gel 9285 Merck was used for column chromatography. Spectra were recorded with the following instruments. IR, Perkin-Elmer $580 \mathrm{~B} ;{ }^{1} \mathrm{H}$ NMR, JEOL FX-100 and Bruker WM-400 spectrome-
ters ( $\delta \mathrm{ppm} / \mathrm{TMS}$ ); mass spectra, Finnigan 3002. The syntheses of $\left[\mathrm{CpCp}^{\prime} \mathrm{Ti}(\mathrm{OAr}) \mathrm{Cl}\right]\left(\mathbf{1}, \mathbf{c}^{\prime}\right)$ and ( $\left.\mathbf{4 c}, \mathbf{c}^{\prime}\right)$ are described in Ref. [4].

### 3.1. Syntheses of $\left[C p C p^{\prime} T i(O A r) X\right]\left(\mathbf{l a}, \boldsymbol{a}^{\prime}\right)$ and $\left(\mathbf{l}, \boldsymbol{b}^{\prime}\right)$

## 1a,a': $\mathbf{X}=\mathrm{NCO}$

In a typical experiment, a solution of $\left[\mathrm{CpCp}^{\prime}-\right.$ $\mathrm{Ti}(\mathrm{NCO})_{2}$ ] [10] ( $555 \mathrm{mg}, 1.75 \mathrm{mmol}$ ) in $25 \mathrm{~cm}^{3}$ of dry benzene was warmed at reflux. Excess $\mathrm{NaNH}_{2}$ was then added. To the resulting material, a solution of $2,6-\mathrm{Me}_{2} \mathrm{C}_{6} \mathrm{H}_{3} \mathrm{OH}$ ( $213 \mathrm{mg}, 1.75 \mathrm{mmol}$ ) in $20 \mathrm{~cm}^{3}$ of benzene was added dropwise. The mixture was stirred 30 min at $80^{\circ} \mathrm{C}$ the progress of this reaction was monitored by TLC; eluent: benzene / hexane / diethyl ether, 6:4:0.3). After filtration through Celite, the filtrate was evaporated to dryness under reduced pressure. The crude product was purified by thin layer chromatography followed by crystallisation from diethyl ether/pentane. This purification afforded successively, in order of decreasing $\mathrm{R}_{\mathrm{f}}$ : 295 mg of red crystals of $\mathbf{1 a}{ }^{\prime}$ in $43 \%$ yield, m.p. $180^{\circ} \mathrm{C}$, and 130 mg of deep-red crystals of 1 a in $18 \%$ yield, m.p. $202^{\circ} \mathrm{C}$.
1b,b': X = NCS
$\left[\mathrm{CpCp}^{\prime} \mathrm{Ti}(\mathrm{NCS})_{2}\right][11]$ using analogous reaction conditions afforded the following compounds in order of decreasing $R_{f}$ : 1b' as red crystals (yield $21 \%$ ), m.p. $148^{\circ} \mathrm{C}$, and 1 b as red crystals (yield $14 \%$ ), m.p. $193^{\circ} \mathrm{C}$.

### 3.2. Synthesis of $\left[C p C p^{\prime} T i B r X\right]\left(2 a, a^{\prime}\right)$ and $\left(2 b, b^{\prime}\right)$

2a,a': X = NCO
In a typical reaction, a solution of HBr in benzene was added slowly to a solution of complex 1a, m.p. $202^{\circ} \mathrm{C}$ ( $123.3 \mathrm{mg}, 0.310 \mathrm{mmol}$ ) in $5 \mathrm{~cm}^{3}$ of benzene

s: singlet; d: doublet; t: triplet; sp: septuplet.
while stirring at room temperature. The progress of this reaction was monitored by TLC; eluent: benzene. Once the characteristic red starting material had disappeared, the addition of hydrobromic acid was stopped to limit the formation of the symmetric $\left[\mathrm{CpCp}^{\prime} \mathrm{TiBr}_{2}\right]$. Removal of the solvent gave a residue which was washed repeatedly with pentane to eliminate the 2,6 $\mathrm{Me}_{2} \mathrm{C}_{6} \mathrm{H}_{3} \mathrm{OH}$ formed during the reaction. This purification afforded complex 2 a ( 96 mg ; yield $86.5 \%$ ) as red-brown crystals m.p. $172^{\circ} \mathrm{C}$.

Treatment of $1 \mathbf{a}^{\prime}$ m.p. $180^{\circ} \mathrm{C}$, according to the above procedure yielded $65 \%$ of the expected complex $2 \mathbf{a}^{\prime}$ as deep-red crystals.
$\mathbf{2 b ,} \mathbf{b}^{\prime}: \mathbf{X}=\mathrm{NCS}$
These were obtained as brown crystals in the same manner as $\mathbf{2 a}, \mathbf{a}^{\prime}$; and starting from $\mathbf{1 b}$, m.p. $193^{\circ} \mathrm{C}, \mathbf{2 b}$, m.p. $143^{\circ} \mathrm{C}$ (yield $37 \%$ ), was isolated, whereas starting from 1 b , m.p. $148^{\circ} \mathrm{C}, 2 \mathrm{~b}$, m.p. $172^{\circ} \mathrm{C}$ (yield $78 \%$ ) was isolated.

### 3.3. Synthesis of $\left[\mathrm{CpCp}^{\prime} \operatorname{Ti}\left(\mathrm{SC}_{6} \mathrm{H}_{5} X\right)\right]\left(3 a, a^{\prime}\right)$ and $\left(\mathbf{3 b}, \boldsymbol{b}^{\prime}\right)$

3a, $\mathbf{a}^{\prime}: \mathbf{X}=\mathrm{NCO}$
In a dropping funnel containing $5.5 \mathrm{~cm}^{3}$ of a solution of $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{SH}$ in $20 \mathrm{~cm}^{3}$ of dry THF, a stoichiometric quantity of Na wire was added under argon. The white suspension obtained after 12 h was added dropwise to a well stirred THF solution ( $10 \mathrm{~cm}^{3}$ ) of [CpCp' TiNCOBr] (2a'), m.p. $150^{\circ} \mathrm{C}$ ( $150 \mathrm{mg}, 0.421$ mmol ), cooled to $-30^{\circ} \mathrm{C}$. After the starting titanium complex had been consumed (TLC; eluent: hexane/diethyl ether, 70:30), the reaction was stopped to avoid the formation of $\left[\mathrm{CpCp}^{\prime} \mathrm{Ti}(\mathrm{SPh})_{2}\right]^{1}$, which was detected by TLC as a purple material in front of the eluent.

After filtration and removal of the solvent under reduced pressure, a brown-violet solid resulted which was purified by thin-layer chromatography. This, followed by crystallization from hexane, afforded 62 mg of orange crystals of 3 a in $62 \%$ yield, m.p. $126^{\circ} \mathrm{C}$.

Treatment of 2 a, m.p. $172^{\circ} \mathrm{C}$ according to the above procedure, but at $-50^{\circ} \mathrm{C}$, yielded $41 \%$ of the expected mixture of complexes $\mathbf{3 a ^ { \prime }}+\mathbf{3 a}$. Chromatographic separation afforded 43 mg of $\mathbf{3 a ^ { \prime }}$, m.p. $131^{\circ} \mathrm{C}$, and 2 mg of 3a, m.p. $126^{\circ} \mathrm{C}$, in order of decreasing $\mathrm{R}_{\mathrm{f}}$ value.
$\mathbf{3 b}, \mathbf{b}^{\prime}: \mathbf{X}=\mathrm{NCS}$
These were prepared as above, except that the reactions were performed at $-40^{\circ} \mathrm{C}$ and $-15^{\circ} \mathrm{C}$, starting from $\mathbf{2 b}$ and $\mathbf{2} \mathbf{b}^{\prime}$, respectively. After thin layer chro-

matographic purification (eluent: hexane/diethyl ether, $7: 3$ ), with $\mathbf{2 b} \mathbf{b}^{\prime}$ as the starting material, $\mathbf{3 b}^{\prime}$, m.p. $173^{\circ} \mathrm{C}$ was obtained as red needles and $\mathbf{3 b}$ as an oil in the ratio of $99: 1$ (total yield $75 \%$ ). Starting from 2b, the products were $\mathbf{3 b ^ { \prime }}$, m.p. $173^{\circ} \mathrm{C}$, and $\mathbf{3 b}$ as an oil in the ratio of $1: 9$ (total yield $60 \%$ ).

## 4. Conclusions

The crystal structure should be considered as an essential support for dynamic stereochemistry studies. The results presented here clearly indicate the limits of the NMR data-based correlations. The assignment of chirality is generally accurate within the same series, notably 1-2 in this work or 1-3 in Ref. [5]. Caution is advised, however, in correlating structures which belong to different series, especially when a planar chirality is concerned. We recall here the erroneous correlation of the planar chirality reported for the benchrotrenic compounds. The configurations $1 S$ and $1 R$ were proposed for the isomeric ( + )-o-methylbenchrotrenic and ( - )-m-methylbenchrotrenic acids on the basis of the quasi-symmetric curves of the rotatory dispersion and circular dichroism [12]. However, the same chirality was demonstrated for these compounds by X-ray analysis [13].

Finally, we list the complexes corresponding to the general structure I (Fig. 3, Table 7) to facilitate the examination of the stereochemistry of the diastereomers. Structure I also corresponds to the structures of all major diastereomers $I$ of the 1-2 series [4], for which $\mathrm{X}=\mathrm{Cl}$ and $\mathrm{Y}=\mathrm{OAr}\left(2-\mathrm{ClC}_{6} \mathrm{H}_{4} \mathrm{O}\right.$ or $3-\mathrm{Me}-6$ ${ }^{i} \mathrm{PrC}_{6} \mathrm{H}_{3} \mathrm{O}$ ). Faster chromatographic elution of the minor diastereomers of each series was always observed. This behaviour is reversed for complexes of the 1-3 series.

Coordinates and temperature factors for the hydrogen atoms, anisotropic temperature factors for non-hydrogen atoms and a table of observed and calculated structure factors are available from the authors and have been deposited with the Cambridge Crystallographic Data Centre.

[^1]:    ${ }^{2}$ Numbers in parentheses are estimated standard deviations in least significant digits.

[^2]:    ${ }^{\text {a }}$ Average distance between the metal and the centre of gravity of the cyclopentadienyl ring.
    ${ }^{b}$ Average distance between the metal and the carbon atoms of the cyclopentadienyl rings.

[^3]:    This complex was identified by comparison with an authentic sample prepared from $\left[\mathrm{CpCp}^{\prime} \mathrm{TiI}_{2}\right]$ [10]. After removal of solvent, the crude product was purified by flash chromatography (eluent: benzene). The benzene was evaporated to afford $\left[\mathrm{CpCp}^{\prime} \mathrm{Ti}(\mathrm{SPh})_{2}\right]$ (yield $62 \%$ ) as purple crystals, m.p. $180^{\circ} \mathrm{C}$.
