Received 14 March 1994; in revised form 4 April 1994

#### Abstract

Reduction of pentamethylcyclopentadienyldichloroarsine (1) with cobaltocene in $n$-hexane affords dimeric pentamethylcyclopentadienylchloroarsine (2). The reaction of (2) with methyl lithium in ether gives dimeric pentamethylcyclopentadienyl (methyl)arsine (3), whose crystal structure has been determined. The crystal structure of (3) (triclinic, space group $P \overline{1}$, $\left.a=7.345(1), b=8.594(1), c=10.673(1) \AA, \alpha=101.07(1)^{\circ}, \beta=104.56(1)^{\circ}, \gamma=113.69(1)^{\circ}, Z=1\right)$ shows two planes, one determined by two carbon atoms of the pentamethylcyclopentadienyl ligands and the two arsenic atoms, the other from two carbon atoms of the methyl ligands and the two arsenic atoms: these two planes display an angle of $78^{\circ}$ alongside the axis formed by the two arsenic atoms. Compounds 2 and 3 are - to the best of our knowledge - the first examples of asymmetric diarsines which combine two asymmetric arsenic centres.

Keywords: Arsenic; Alkyl; Bulky ligands; Cyclopentadienyl; Group 15; X-ray diffraction

## 1. Introduction

Homonuclear element-element compounds containing As-As bonds have been extensively reported, e.g. cyclopolyarsines (RAs) ${ }_{n}[1-5]$, cyclopolyarsines $\mathrm{R}_{n} \mathrm{As}_{m}$ [6,7], and tetraorganodiarsines $\mathrm{R}_{4} \mathrm{As}_{2}$ [8-9]. Since the 1980's there has been great interest in the investigation of compounds $\mathbf{R}_{4} \mathrm{As}_{2}$ : fitted with suitable organic ligands these molecules may exhibit "secondary contacts" between arsenic atoms of different molecules, exactly the same phenomenon observed in the related distibines and dibismuthines [10-16].

Generally, compounds $\mathrm{R}_{4} \mathrm{E}_{2}(\mathrm{E}=\mathrm{As}, \mathrm{Sb}$ and Bi$)$ can be synthesized 1) by reduction of $\mathrm{R}_{3} \mathrm{E}$ with sodium in liquid ammonia followed by subsequent treatment with 1,2-dichloroethane, 2) by reduction of $\mathrm{R}_{2} \mathrm{EX}$ (X $=$ halogen) with sodium in liquid ammonia and 3) by reacting $\mathbf{R}_{\mathbf{2}} \mathrm{EM}(\mathrm{M}=\mathrm{Li}, \mathrm{Na})$ with $\mathbf{R}_{2} \mathrm{EX}$. Te-

[^0]traphenyldibismuth [17] was synthesized accordingly by reduction of diphenylbismuth chloride with cobaltocene.

(A)

(B)

However, to date only compounds with structures like A can be synthesized and only those organo ele-ment-element compounds have been reported which contain the same organic ligands bonded to the main group elements. The thermochromic behaviour of compounds $\mathrm{R}_{4} \mathrm{E}_{2}$ is strongly dependent on the nature of the organic ligands, therefore it is challenging to attempt to synthesize compounds $R_{4} E_{2}$ with different organic ligands: in this paper we report the first examples of asymmetric substituted diarsines $\left(\mathrm{R}^{1} \mathrm{AsR}^{2}\right)_{2}\left(\mathrm{R}^{1}\right.$
$=\mathrm{Cp}^{*}, \mathrm{R}^{2}=\mathrm{Cl}$ and $\mathrm{CH}_{3}$ ) with structures like B incorporating two asymmetric arsenic centres.

## 2. Results and discussion

Compound 2 was prepared by reduction of 1 with cobaltocene in n-hexane at ambient temperature in high yield ( $78 \%$ ) according to Eq. (1):
$2 \mathrm{Cp}^{\star} \underset{(1)}{\mathrm{AsCl}_{2}}+2 \mathrm{CoCp}_{2} \xrightarrow[20^{\circ} \mathrm{C}]{\text { n-hexane }}$
$\left(\mathrm{Cp}^{*} \mathrm{AsCl}\right)_{2}+2 \mathrm{Cp}_{2} \mathrm{CoCl}$
(2)

2 is very soluble in n-hexane, whereas $\mathrm{Cp}_{2} \mathrm{CoCl}$ is practically insoluble and thus can be easily separated from the reaction mixture. At room temperature 1 cannot be further reduced by cobaltocene to the elusive $\left[\mathrm{Cp}{ }^{\star} \mathrm{As}\right]_{n}$ according to Eq. (2), the reason for this probably is the efficient protection of the As- Cl bonds by the bulky $\mathrm{Cp}^{*}$-ligands:

$$
\begin{equation*}
\left(\mathrm{Cp}^{\star} \mathrm{AsCl}\right)_{2}+2 \mathrm{CoCp}_{2}-/ / \rightarrow^{2} / x_{x}\left(\mathrm{Cp}^{\star} \mathrm{As}\right)_{x}+2 \mathrm{Cp}_{2} \mathrm{CoCl} \tag{2}
\end{equation*}
$$

2 can be recrystallized from $n$-hexane as a yellow, microcrystalline solid, m.p. $130^{\circ} \mathrm{C}$, soluble in inert organic solvents. Rotation around the As-As axis at room temperature is not hindered, but as soon as the temperature decreases, a rotational barrier becomes evident and can be monitored by NMR spectroscopy. In the ${ }^{1} \mathrm{H}$-NMR spectrum of 2 at 298 K there is only one signal ( $\delta=1.74 \mathrm{ppm}$ ) for all hydrogen atoms, and in the ${ }^{13} \mathrm{C}$-NMR spectrum two signals (one at $\delta=11.92$ ppm for the methyl carbon atoms and another at $\delta=126.95 \mathrm{ppm}$ for the cyclopentadienyl ring carbon atoms) are observed. Lowering the temperature to 233 $K$ gives rise to five signals in the ${ }^{1} \mathrm{H}$-NMR spectrum for the methyl hydrogen atoms and to nine signals in the ${ }^{13} \mathrm{C}$-NMR spectrum for the $\mathrm{Cp}{ }^{\star}$ and methyl carbon atoms (one signal for the methylene carbon atom of cyclopentadienyl ring maybe obscured by signals for the THF-solvent carbon atoms in the range from $\delta=$ 66.96 to 67.84 ppm ).

3 was prepared by the reaction of 2 with methyl lithium in ether in $71 \%$ yield according to Eq. (3):

$$
\underset{(2)}{\left(\mathrm{Cp}^{*} \mathrm{AsCl}\right)_{2}}+2 \mathrm{CH}_{3} \mathrm{Li}_{20^{\circ} \mathrm{C}}^{\mathrm{ET}_{2} \mathrm{O}} \underset{\text { (3) }}{\left(\mathrm{Cp}^{\star} \mathrm{AsCH}_{3}\right)_{2}+2 \mathrm{LiCl}}
$$

3 is readily soluble in all inert organic solvents but can be recrystallized from $n$-hexane as yellow crystals, m.p. $96^{\circ} \mathrm{C}$. The EI mass spectra exhibit the molecular ion at
$m / e=450$, and supply all peaks required for a reasonable interpretation of the fragmention scheme of 3 . In the NMR spectrum six signals for the methyl hydrogen atoms and ten signals for the methyl and $\mathrm{Cp}{ }^{*}$ carbon atoms (two signals of two methyl carbon atoms are located together at $\delta=11.96 \mathrm{ppm}$ ) are displayed even at room temperature, and the ${ }^{13} \mathrm{C}$-NMR spectrum at 203 K gives eleven signals for all carbon atoms, indicating that free rotation around the As-As axis is already blocked at ambient temperature. Clearly, substitution of the two chlorine atoms in 2 by two bulkier methyl ligands in 3 leads to the observed phenomena in the NMR spectra.

These results strongly support our idea that the synthetic method described above can be extended to the preparation of organoelement compounds with structures like (C) and (D) (e.g. $E=P, A s, S b$ and $B i$ ):

Assuming that each lone pair at the arsenic atoms in 3 occupies a spatial segment, we can then assign to each arsenic atom four different ligands: due to the stabilizing bulky $\mathrm{Cp}^{\star}$ ligands only the centrosymmetric form (D) was obtained. However, if the $R^{1}$ and $R^{2}$ ligands are properly designed the alternative molecule (C) seems to be a feasible perspective.

### 2.1. Crystal structure solution of 3

The crystal structure of 3 was determined by single crystal X-ray diffraction studies at 223 K . Figs. 1 and 2 represent a plot of the molecular structure and a stereo plot of the unit cell; crystaliographic data are listed in Table 1. Some selected bond distances, bond angles plus torsions as well as atomic coordinates and

Fig. 1. Molecular structure of 3.

Fig. 2. Unit cell of 3.
equivalent isotropic temperature parameters are given in Tables 2 and 3 respectively.

Each of the arsenic atoms in 3 displays a distorted pyramidal coordination sphere in which each arsenic atom is linked to three different ligands, namely to the carbon atom of a methyl group, to a carbon atom of the $\mathrm{Cp}^{*}$ ligand and to another arsenic atom. The bond

Supplementary material to the crystal structure investigation may be obtained from the Fachinformationszentrum Karlsruhe, Gesellschaft für wissenschaftlich-technische Information mbH, D-76433 Eggen-stein-Leopoldshafen 2, Germany, under specification of deposit no. CSD380064, names of the authors and the journal reference.

Table 2
Selected bond distances ( $\AA$ ), bond angles $\left({ }^{\circ}\right)$ and torsions $\left({ }^{\circ}\right)$ of 3 (with standard deviations in parentheses)

angles $\mathrm{C}(6)-\mathrm{As}-\mathrm{C}(1), \mathrm{C}(1)-\mathrm{As}-\mathrm{As}$ and $\mathrm{C}(6)-\mathrm{As}-\mathrm{As}$ are $100.6^{\circ}, 98.6^{\circ}$ and $97.5^{\circ}$, respectively, each angle is considerably smaller than tetrahedral, indicating that the lone pairs at the arsenic atoms are predominantly of s -character.

Two planes can be defined in a molecule of compound 3: one plane includes two carbon atoms of the pentamethylcyclopentadienyl ligands and two arsenic atoms, the other plane two carbon atoms of the methyl ligands and two arsenic atoms. These two planes embrace an angle of $78^{\circ}$ along the axis defined by the two arsenic atoms.

The As-As distance in $\mathbf{3}$ of $2.440(1) \AA$ is in the same range as those already reported in other diarsines. In 3 we observed two markedly different As-C distances: onc with $1.982(3) \AA$ for the $\mathrm{As}-\mathrm{C}$ (methyl ligand) distance is among the average values of already known arsenic compounds; the other with $2.043(3) \AA$ for the As-C (pentamethylcyclopentadienyl ligand) distance, however, is somewhat longer than the As-C (methyl ligand) bond distance but compares well with the data found for $\mathrm{As}\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)_{3}(1.99-2.03 \AA)$ [22] or $\mathrm{C}_{5}\left(\mathrm{CH}_{3}\right)_{5}$ $\mathrm{AsCl}_{2}(2.01 \AA$ ) [22]; a comparison of relevant As-Asand As-C distances is given in Table 4.

For the intermolecular As-As distances we observed a mean value of about $4.95 \AA$, considerably longer than the sum of the van der Waals radii [23] and that of the covalent radii from Pauling [24] of $4.00 \AA$;

in conclusion, to our belief there is no "secondary bonding" in compound 3

Fig. 3 shows a Newman projection of 3: the two bulky pentamethylcyclopentadienyl ligands are transpositioned with reference to the As-As axis (assuming hindered rotation) in order to minimize steric repulsion.

## 3. Experimental section

All manipulations were carried out under an argon atmosphere. Solvents werc dried by standard methods and were freshly distilled prior to use. $\mathrm{Cp}^{*} \mathrm{AsCl}_{2}$ was prepared according to the literature [25]. Methyl lithium was purchased from Aldrich. CH -analyses were performed on a CHN-Rapid automat (Heraeus); NMR spectra were recorded on a Bruker AMX-500 (500 $\mathrm{MHz})$ spectrometer. EI mass spectra were obtained with a Varian MAT CH 7A spectrometer, IR spectra were recorded on a Perkin-Elmer spectrometer.

### 3.1. Synthesis of 2

A solution of cobaltocene ( $4.53 \mathrm{~g} ; 24 \mathrm{mmol}$ ) in n -hexane ( 100 ml ) was added to a stirred solution of 1 $(3.37 \mathrm{~g} ; 12 \mathrm{mmol})$ at $-78^{\circ} \mathrm{C}$ for 1 h . After 1 h stirring at

(a)

(b)

Fig. 3. Newman projection of 3.
this temperature, the mixture was allowed to warm to $0^{\circ} \mathrm{C}$ and stirred for another 20 h . The originally red coloured solution turned to yellow and a precipitate was formed; the mixture was then stirred at room temperature for an additional 10 h . The solid was filtered and the yellow solution concentrated to about 50 ml and cooled to $-30^{\circ} \mathrm{C}$. After 50 h a first crop of yellow crystails was formed, separated by filtration and dried in vacuo; m.p. $130^{\circ} \mathrm{C}$, yield 2.30 g ( 4.6 mmol , $78 \%$ ). Found (\%): C, 48.74; H, 6.14; As, 31.57 ; Cl, 14.48. $\mathrm{C}_{20} \mathrm{H}_{30} \mathrm{As}_{2} \mathrm{Cl}_{2}$ calc.: C, 48.90 ; $\mathrm{H}, 6.17$; As, 30.15 ; $\mathrm{Cl}, 14.44 \%$. ${ }^{\mathrm{H}}$-NMR (THF- $d_{8}, 298 \mathrm{~K}$ ): $\delta$ ( ppm ): 1.74 , $\mathrm{s}, 15 \mathrm{H},-\mathrm{CH}_{3}{ }^{13}{ }^{13} \mathrm{C}$-NMR (THF- $d_{8}, 298 \mathrm{~K}$ ): $11.92,-\mathrm{CH}_{3}$; $126.95,-C_{5} \mathrm{H}_{5}{ }^{1} \mathrm{H}-\mathrm{NMR}$ (THF- $d_{8}, 233 \mathrm{~K}$ ): $1.42, \mathrm{~s}, 3 \mathrm{H}$, As-C $H_{3} ; 1.73$, s, $3 \mathrm{H},-\mathrm{CH}_{3} ; 1.76, \mathrm{~s}, 3 \mathrm{H},-\mathrm{CH}_{3} ; 1.79$, s, $3 \mathrm{H},-\mathrm{CH}_{3} ; 1.84,(\mathrm{~s}, 3 \mathrm{H}),-\mathrm{CH}_{3}{ }^{13} \mathrm{C}-\mathrm{NMR}$ : (THF- $\mathrm{d}_{8}$, 233 K ): $9.70,-\mathrm{CH}_{3} ; 10.48-\mathrm{CH}_{3} ; 11.91-\mathrm{CH}_{3} ; 12.55$, $-\mathrm{CH}_{3} ; 15.30,-\mathrm{C}=\mathrm{C}-; 130.80,-\mathrm{C}=\mathrm{C}-; 133.46,-\mathrm{C}=\mathrm{C}-;$ $142.39,-\mathrm{C}=\mathrm{C}-; 147.93,-\mathrm{C}=\mathrm{C}-$. ### 3.2. Synthesis of 3

A solution of methyl lithium in diethyl ether (4.4 mmol methyl lithium) was added to a stirred solution of $2(1.10 \mathrm{~g}, 2.2 \mathrm{mmol})$ in diethyl ether ( 50 ml ) at $-70^{\circ} \mathrm{C}$ for 5 min and then stirred for 2 h . After warming to room temperature the mixture was stirred for 40 h . A precipitate was formed; the solvents were evaporated in vacuo and the residue extracted with petrol ether ( 80 ml ). After filtration, the yellow filtrate was concentrated in vacuo until the first crystals appeared. Cooling this concentrated solution to $-30^{\circ} \mathrm{C}$ for 48 h affords yellow crystals which were separated and dried in vacuo; m.p. $96^{\circ} \mathrm{C}$, yield $0.70 \mathrm{~g}(1.6 \mathrm{mmol}$, $71 \%$ ).

Found (\%): C, 57.45; H, 7.88. $\mathrm{C}_{20} \mathrm{H}_{30} \mathrm{As}_{2}\left(\mathrm{CH}_{3}\right)_{2}$ calc.
