#### Abstract

Reaction of $\left[\mathrm{MX}(\mathrm{CO})_{2}\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right](\mathrm{M}=\mathrm{Mo}, \mathrm{X}=\mathrm{Br} ; \mathrm{M}=\mathrm{W}, \mathrm{X}=\mathrm{I})$ with two equivalents of $\mathrm{CNBu}^{t}$ in toluene affords the trihapto-bonded cycloheptatrienyl complexes $\left[\mathrm{MX}(\mathrm{CO})_{2}\left(\mathrm{CNBu}^{t}\right)_{2}\left(\eta^{3}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right](\mathbf{1}, \mathrm{M}=\mathrm{Mo}, \mathrm{X}=\mathrm{Br} ; \mathbf{2}, \mathrm{M}=\mathrm{W}, \mathrm{X}=\mathrm{I})$. The X -ray crystal structure of $\mathbf{2}$ reveals a pseudo-octahedral molecular geometry with an asymmetric ligand arrangement at tungsten in which one $\mathrm{CNBu}^{t}$ is located trans to the $\eta^{3}-\mathrm{C}_{7} \mathrm{H}_{7}$ ring. Treatment of 2 with tetracyanoethene results in 1,4-cycloaddition at the $\eta^{3}-\mathrm{C}_{7} \mathrm{H}_{7}$ ring to give $\left[\mathrm{WI}(\mathrm{CO})_{2}\left(\mathrm{CNBu}^{t}\right)_{2}\left\{\eta^{3}-\mathrm{C}_{9} \mathrm{H}_{7}(\mathrm{CN})_{4}\right\}\right]$, 3. The principal reaction type of the molybdenum complex $\mathbf{1}$ is loss of carbonyl and bromide ligands to afford substituted products $\left[\mathrm{MoBr}\left(\mathrm{CNBu}^{t}\right)_{2}\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right] 4$ or $\left[\mathrm{Mo}(\mathrm{CO})\left(\mathrm{CNBu}^{t}\right)_{2}\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right] \mathrm{Br}$. Reaction of $\left[\operatorname{MoBr}(\mathrm{CO})_{2}\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right]$ with one equivalent of $\mathrm{CNBu}^{t}$ in toluene at $60^{\circ} \mathrm{C}$ affords $\left[\mathrm{MoBr}(\mathrm{CO})\left(\mathrm{CNBu}^{t}\right)\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right]$, $\mathbf{5}$, which is a precursor to $\left[\mathrm{Mo}(\mathrm{CO})\left(\mathrm{CNBu}^{t}\right)(\mathrm{NCMe})\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right]\left[\mathrm{BF}_{4}\right]$, 6, by reaction with $\mathrm{Ag}\left[\mathrm{BF}_{4}\right]$ in acetonitrile. In contrast with the parent dicarbonyl systems $\left[\mathrm{MoX}(\mathrm{CO})_{2}\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right]$, complexes of the $\mathrm{Mo}(\mathrm{CO})\left(\mathrm{CNBu}^{t}\right)\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)$ auxiliary, $\mathbf{5}$ and $\mathbf{6}$, do not afford observable $\eta^{3}-\mathrm{C}_{7} \mathrm{H}_{7}$ products by ligand addition at the molybdenum centre. © 1998 Elsevier Science S.A. ## 1. Introduction

Complexes of the general formulation $\left[\mathrm{MX}(\mathrm{CO})_{2}{ }^{-}\right.$ $\mathrm{L}_{2}^{\prime}\left(\eta^{3}\right.$-allyl $\left.)\right][\mathrm{M}=\mathrm{Mo}$ or $\mathrm{W} ; \mathrm{X}=$ halide or pseudohalide; $\mathrm{L}^{\prime}=\mathrm{NCMe}, \mathrm{L}_{2}^{\prime}=\mathrm{Ph}_{2} \mathrm{PCH}_{2} \mathrm{CH}_{2} \mathrm{PPh}_{2}$ (dppe), 2,2'-bipyridine (bipy), etc.] represent an important area of the organometallic chemistry of molybdenum and tungsten and investigations with an extensive range of $\eta^{3}$-allyl ligands (including allyl $=\mathrm{C}_{3} \mathrm{H}_{5}$ [1], pentadienyl [2], hexadienyl [3], cyclopentenoyl [4], cycloheptadienyl [5], cyclooctadienyl [6] or cycloheptatrienyl) have been reported. In a series of papers [7-11], we have examined the synthesis, structure, fluxional properties and reactivity of $\eta^{3}$-cycloheptatrienyl complexes of the type $\left[\mathrm{MX}(\mathrm{CO})_{2} \mathrm{~L}_{2}^{\prime}\left(\eta^{3}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right](\mathrm{M}=\mathrm{Mo}$ or W$)$ and related cationic derivatives. The majority of this work

[^0]has employed the chelates bipy, dppe and dppm $\left(\mathrm{Ph}_{2} \mathrm{PCH}_{2} \mathrm{PPh}_{2}\right)$ as supporting $\mathrm{L}_{2}^{\prime}$ groups and these appear to define strong preferences for the geometric arrangement of ligands at the metal centre. In search of a more structurally flexible system, we examined the feasibility of employing monodentate $\mathrm{L}^{\prime}$ ligands as supporting groups. In fact the options for suitable mondentate $\mathrm{L}^{\prime}$ ligands are fairly restricted. Ligands such as NCMe are too labile (especially in $\eta^{3}$-cycloheptatrienyl complexes [11]) to provide a stable $\mathrm{MX}(\mathrm{CO})_{2} \mathrm{~L}_{2}^{\prime}$ auxiliary and, whilst $[\mathrm{Mo}-$ $\left.\mathrm{Cl}(\mathrm{CO})_{2}\left\{\mathrm{P}(\mathrm{OMe})_{3}\right\}_{2}\left(\eta^{3}-\mathrm{C}_{3} \mathrm{H}_{5}\right)\right]$ is known [12], in the cycloheptatrienyl system reaction of $\left[\mathrm{MX}(\mathrm{CO})_{2}\left(\eta^{7}-\right.\right.$ $\left.\left.\mathrm{C}_{7} \mathrm{H}_{7}\right)\right]\left(\mathrm{M}=\mathrm{Mo}\right.$ or $\mathrm{W} ; \mathrm{X}=$ halide ) with $\mathrm{PR}_{3}(\mathrm{R}=\mathrm{Me}$ or OMe ) affords $\left[\mathrm{MX}(\mathrm{CO})\left(\mathrm{PR}_{3}\right)\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right.$ ] [13]. However a report [14] on the synthesis of [Mo-$\left.\mathrm{Cl}(\mathrm{CO})_{2}\left(\mathrm{CNBu}^{\prime}\right)_{2}\left(\eta^{3}-\mathrm{C}_{3} \mathrm{H}_{5}\right)\right]$ prompted the successful use of $\mathrm{CNBu}^{t}$ as a supporting $\mathrm{L}^{\prime}$ ligand in the cyclohep-
tatrienyl system and this paper describes the structure and properties of the resulting $\left[\mathrm{MX}(\mathrm{CO})_{2}\left(\mathrm{CNBu}^{7}\right)_{2}\left(\eta^{3}-\right.\right.$ $\mathrm{C}_{7} \mathrm{H}_{7}$ )] complexes.

## 2. Results and discussion

Reaction of $\left[\mathrm{MX}(\mathrm{CO})_{2}\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right](\mathrm{M}=\mathrm{Mo}, \mathrm{X}=\mathrm{Br}$; $\mathrm{M}=\mathrm{W}, \mathrm{X}=\mathrm{I}$ ) with two equivalents of $\mathrm{CNBu}^{t}$ in toluene resulted in a colour change from green to red and the formation of the trihapto-bonded cycloheptatrienyl complexes $\left[\mathrm{MX}(\mathrm{CO})_{2}\left(\mathrm{CNBu}^{t}\right)_{2}\left(\eta^{3}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right]$ (1, $\mathrm{M}=\mathrm{Mo}, \mathrm{X}=\mathrm{Br} ; \mathbf{2}, \mathrm{M}=\mathrm{W}, \mathrm{X}=\mathrm{I}$; see Scheme 1 for specific reaction conditions). The preparation and purification of the molybdenum derivative 1 were carried out at low temperature to avoid reversion to $\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}$ products through loss of labile Br or CO ligands (see later). Details of the characterisation of these and subsequently described complexes are presented in Table 1 (microanalytical and IR spectroscopic data) and Table $2\left({ }^{1} \mathrm{H}-\right.$ and ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$-NMR spectroscopic data). The $\eta^{7} \rightarrow \eta^{3}$ hapticity conversion at the cycloheptatrienyl ring is accompanied by characteristic spectroscopic changes in $v(\mathrm{CO})$ in the IR spectrum and $\delta\left(\mathrm{C}_{7} \mathrm{H}_{7}\right)$ in the ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}-$ NMR spectrum [11].
We have previously reported X-ray structural studies on the $\eta^{3}$-cycloheptatrienyl complexes $\left[\mathrm{MoX}(\mathrm{CO})_{2}-\right.$ $\left.\mathrm{L}_{2}^{\prime}\left(\eta^{3}-\mathrm{C}_{7} \mathrm{H}_{6} \mathrm{R}\right)\right] \quad\left(\mathrm{X}=\mathrm{NCS}, \mathrm{L}_{2}^{\prime}=\right.$ bipy, $\mathrm{R}=\mathrm{H} ; \mathrm{X}=\mathrm{Cl}$, $\mathrm{L}_{2}^{\prime}=$ dppe, $\mathrm{R}=\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{~F}-4$ [11]) which, in common with a wide range of complexes of the type $\left[\mathrm{MX}(\mathrm{CO})_{2} \mathrm{~L}_{2}^{\prime}\left(\eta^{3}\right.\right.$-allyl)] ( $L_{2}^{\prime}=$ bidentate chelate ligand) demonstrate a marked structural dependence upon $L_{2}^{\prime}$. However synthetic and structural investigations on complexes $\left[\mathrm{MX}(\mathrm{CO})_{2} \mathrm{~L}_{2}^{\prime}\left(\eta^{3}\right.\right.$-allyl) $] \quad\left(\mathrm{L}^{\prime}=\right.$ monodentate ligand $)$ are much more limited and, with the exception of $\mathrm{L}^{\prime}=$ NCMe , we are aware only of crystallographic characterisations of $\left[\mathrm{MoCl}(\mathrm{CO})_{2}\left\{\mathrm{P}(\mathrm{OMe})_{3}\right\}_{2}\left(\eta^{3}-\mathrm{C}_{3} \mathrm{H}_{5}\right)\right] \quad[12]$ and $\left[\mathrm{MoBr}(\mathrm{CO})_{2}\left(\mathrm{C}_{3} \mathrm{H}_{4} \mathrm{~N}_{2}\right)_{2}\left(\eta^{3}-1-\mathrm{Ph}-\mathrm{C}_{3} \mathrm{H}_{4}\right)\right] \quad\left(\mathrm{C}_{3} \mathrm{H}_{4}-\right.$ $\mathrm{N}_{2}=$ pyrazole) [15]. The structure type of complexes $\mathbf{1}$ and 2 was therefore of interest, further to define the ligand dependent molecular geometry of the $\left[\mathrm{MX}(\mathrm{CO})_{2} \mathrm{~L}_{2}^{\prime}\left(\eta^{3}\right.\right.$-allyl)] system. Complex 2 was selected for investigation because of the enhanced stability of the tungsten derivative with respect to reversion to $\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}$ products and because it provides the first crystallographically characterised example of the cycloheptatrienyl ligand bonded trihapto to tungsten in a monometallic complex.

The molecular geometry of $\left[\mathrm{WI}(\mathrm{CO})_{2}\left(\mathrm{CNBu}^{1}\right)_{2}\left(\eta^{3}-\right.\right.$ $\left.\left.\mathrm{C}_{7} \mathrm{H}_{7}\right)\right] 2$ and the atomic numbering scheme employed are illustrated in Fig. 1 and details of important bond lengths and angles are presented in Table 3. The complex adopts a pseudo-octahedral geometry, with one $\mathrm{CNBu}^{t}$ ligand located trans to the $\eta^{3}-\mathrm{C}_{7} \mathrm{H}_{7}$ ring and the remaining ligands occupying an approximately equatorial plane, the carbonyl ligands being placed mutually
cis. An asymmetric ligand arrangement similar to that of $\left[\operatorname{MoBr}(\mathrm{CO})_{2}\left(\mathrm{C}_{3} \mathrm{H}_{4} \mathrm{~N}_{2}\right)_{2}\left(\eta^{3}-1-\mathrm{Ph}-\mathrm{C}_{3} \mathrm{H}_{4}\right)\right]$ is therefore adopted and it appears that despite the similar $\pi$-acceptor nature of CO and $\mathrm{CNBu}^{t}$ ligands, location of CO trans to the $\eta^{3}$-allyl type ligand is still the least favourable option. Some structural features of complex 2 are in common with the vast majority of systems $\left[\mathrm{MX}(\mathrm{CO})_{2} \mathrm{~L}_{2}^{\prime}\left(\eta^{3}\right.\right.$-allyl)] including the location of the two carbonyls directly beneath the terminal carbons of the $\eta^{3}$-allyl fragment and a shortening of the $\mathrm{W}-\mathrm{C}$ (central allyl) distance by comparison with the $\mathrm{W}-\mathrm{C}$ (terminal allyl) bonds. The $\eta^{3}$-cycloheptatrienyl ring is folded about the planes defined by $[\mathrm{C}(2)-\mathrm{C}(1)-\mathrm{C}(7)]$ and $[C(2)-C(3)-C(4)-C(5)-C(6)-C(7)]$ with the angle between the planes $\left(37^{\circ}\right)$ similar to those reported for $\left[\mathrm{Mo}(\mathrm{CO})_{2}\left(\eta^{3}-\mathrm{C}_{7} \mathrm{H}_{7}\right) \mathrm{Cp}\right] \quad\left(36^{\circ}\right) \quad[16], \quad\left[\mathrm{Mo}(\mathrm{NCS})(\mathrm{CO})_{2}-\right.$ (bipy) $\left.\left(\eta^{3}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right] \quad\left(32^{\circ}\right)$ and $\left[\mathrm{MoCl}(\mathrm{CO})_{2}(\mathrm{dppe})\left(\eta^{3}-\right.\right.$ $\left.\left.\mathrm{C}_{7} \mathrm{H}_{6} \mathrm{C}_{6} \mathrm{H}_{4} \mathrm{~F}-4\right)\right]\left(33^{\circ}\right)$ [11].
${ }^{13} \mathrm{C}$-NMR data for $\mathbf{1}$ and $\mathbf{2}$ suggest that the asymmetric ligand arrangement deduced for $\mathbf{2}$ in the solid state is retained in solution. The room temperature (r.t.) ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}-\mathrm{NMR}$ spectra of $\mathbf{1}$ and $\mathbf{2}$ each show a singlet for the $\eta^{3}-\mathrm{C}_{7} \mathrm{H}_{7}$ ring consistent with a 1,2 -shift process [ 8,17$]$ which renders equivalent all positions in the cycloheptatrienyl ring. However each complex exhibits two discrete carbonyl resonances and, although slightly broad at r.t., two resonances for each of the $\mathrm{CNCMe}_{3}$ and CNCMe 3 carbons. This inequivalence of both carbonyl and both isocyanide ligands is clearly consistent with the solid state structure of $\mathbf{2}$. Further spectroscopic evidence for an asymmetric structure is provided by the variable temperature ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$-NMR spectrum of $\mathbf{2}$. At $-30^{\circ} \mathrm{C}$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$, the resonances assigned to the carbonyl and isocyanide ligands of $\mathbf{2}$ are sharpened by comparison with the r.t. spectrum but the resonance attributed to the cycloheptatrienyl ring is notably broadened, consistent with a reduced rate of the 1,2shift process. At $-80^{\circ} \mathrm{C}$, the signal at 102 ppm assigned to the $\mathrm{C}_{7} \mathrm{H}_{7}$ ring is absent but the region of the spectrum from 120 to 140 ppm exhibits six resonances ( $\delta, \mathrm{CD}_{2} \mathrm{Cl}_{2}: 138.3,137.5,130.7,128.2,125.2,124.7$ ) attributable to two $C \mathrm{NBu}^{t}$ carbons and the four diene carbons ( $\mathrm{C}_{3}$ and $\mathrm{C}_{4}$ - see Scheme 1 for NMR numbering system) of the cycloheptatrienyl ring. The inequivalence of all four diene carbons is again consistent with an asymmetric ligand arrangement at the metal centre.

Our previous investigations on complexes of the general type $\left[\mathrm{MX}(\mathrm{CO})_{2} \mathrm{~L}_{2}^{\prime}\left(\eta^{3}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right]$ have established two principal reactivity types. Where $\mathrm{M}=\mathrm{Mo}$, the dominant reaction type is reversion to an $\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}$ product via loss of CO or X ligands. However, where $\mathrm{M}=\mathrm{W}$ and the $\mathrm{W}-\mathrm{X}$ bond is relatively strong $(\mathrm{X}=\mathrm{I})$, the complexes are resistant to fission of $\mathrm{W}-\mathrm{CO}$ and $\mathrm{W}-\mathrm{X}$ bonds so permitting reactions at the $\eta^{3}-\mathrm{C}_{7} \mathrm{H}_{7}$ ring to be explored. The derivatives prepared in the current work were designed to promote these two contrasting reactiv-

Scheme 1. Reagents and conditions: (i) $\mathrm{M}=\mathrm{Mo}, \mathrm{X}=\mathrm{Br}$; $2 \mathrm{CNBu}^{t}$ in toluene, $0^{\circ} \mathrm{C}, 30 \mathrm{~min} . \mathrm{M}=\mathrm{W}, \mathrm{X}=\mathrm{I} ; 2 \mathrm{CNBu}^{t}$ in toluene, r.t., 4.5 h . (ii) $\mathrm{M}=\mathrm{W}, \mathrm{X}=\mathrm{I}$; tcne in $\mathrm{CH}_{2} \mathrm{Cl}_{2}, 2 \mathrm{~h}$. (iii) $\mathrm{M}=\mathrm{Mo}, \mathrm{X}=\mathrm{Br}$; reflux in toluene, 30 min . (iv) $\mathrm{M}=\mathrm{Mo}, \mathrm{X}=\mathrm{Br}$; $\mathrm{CNBu}^{t}$ (one equivalent) in toluene ( $60^{\circ} \mathrm{C}$ ). (v) $\mathrm{Ag}\left[\mathrm{BF}_{4}\right]$ in $\mathrm{CH}_{3} \mathrm{CN}, 30 \mathrm{~min}$.
ity types; thus the molybdenum derivative $\mathbf{1}$ with a weakly bonded bromide ligand should readily afford ligand substituted $\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}$ products whereas the tungsten complex 2, should be stable in the $\eta^{3}-\mathrm{C}_{7} \mathrm{H}_{7}$ form.

One reaction type, apparently exclusive to tungsten derivatives, is addition of tetracyanoethene (tcne) to the $\eta^{3}-\mathrm{C}_{7} \mathrm{H}_{7}$ ring. Thus we have demonstrated previously that reaction of $\left[\mathrm{WI}(\mathrm{CO})_{2} \mathrm{~L}_{2}^{\prime}\left(\eta^{3}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right]\left(\mathrm{L}_{2}^{\prime}=\right.$ dppe or dppm) with tcne affords the isolable adducts $\left[\mathrm{WI}(\mathrm{CO})_{2} \mathrm{~L}_{2}^{\prime}\left\{\eta^{3}-\mathrm{C}_{9} \mathrm{H}_{7}(\mathrm{CN})_{4}\right\}\right]$ with retention of an asymmetric ligand arrangement at the coordinated $\mathrm{WI}(\mathrm{CO})_{2} \mathrm{~L}_{2}^{\prime}$ metal group [8]. Similarly, reaction of $\left[\mathrm{WI}(\mathrm{CO})_{2}\left(\mathrm{CNBu}^{1}\right)_{2}\left(\eta^{3}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right]$, 2 with tcne affords
$\left[\mathrm{WI}(\mathrm{CO})_{2}\left(\mathrm{CNBu}^{1}\right)_{2}\left\{\eta^{3}-\mathrm{C}_{9} \mathrm{H}_{7}(\mathrm{CN})_{4}\right\}\right], 3$ as a deep purple solid. The ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$-NMR data for 3 are fully consistent with the 1,4 -addition of tene to the cycloheptatrienyl ring, with the separate carbon environments of the $\mathrm{C}_{9} \mathrm{H}_{7}(\mathrm{CN})_{4}$ ligand clearly discernable. However, by comparison with the ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$-NMR spectra of the phosphine analogues $\left[\mathrm{WI}(\mathrm{CO})_{2} \mathrm{~L}_{2}^{\prime}\left(\eta^{3}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right]\left(\mathrm{L}_{2}^{\prime}=\right.$ dppe or dppm), the data for $\mathbf{3}$ are unexpectedly simple. Thus, whereas for $\left[\mathrm{WI}(\mathrm{CO})_{2}(\mathrm{dppm})\left\{\eta^{3}-\mathrm{C}_{9} \mathrm{H}_{7}(\mathrm{CN})_{4}\right\}\right]$, the asymmetry of the $\mathrm{WI}(\mathrm{CO})_{2}(\mathrm{dppm})$ ligand arrangement is clear from the inequivalence of carbonyl ligands and otherwise identical carbons in the $\mathrm{C}_{9} \mathrm{H}_{7}(\mathrm{CN})_{4}$ ligand, in 3 both at r.t. and at $-80^{\circ} \mathrm{C}$, only seven discrete

Fig. 1. The molecular structure of complex 2 showing the crystallographic numbering scheme ( H atoms omitted for clarity).
resonances are attributable to the $\mathrm{C}_{9} \mathrm{H}_{7}(\mathrm{CN})_{4}$ ligand and moreover (in contrast with $\mathbf{2}$ ) the pairs of carbonyl and $\mathrm{CNBu}^{t}$ ligands appear to be equivalent. Further evidence that the course of the reaction between tene and 2 differs slightly from that with $\left[\mathrm{WI}(\mathrm{CO})_{2} \mathrm{~L}_{2}^{\prime}\left(\eta^{3}-\right.\right.$ $\left.\left.\mathrm{C}_{7} \mathrm{H}_{7}\right)\right]\left(\mathrm{L}_{2}^{\prime}=\right.$ dppe or dppm $)$ is provided by IR data; the formation of $\mathbf{3}$ from $\mathbf{2}$ is accompanied by an increase in $v(\mathrm{CO})_{\text {average }}$ by $46 \mathrm{~cm}^{-1}$ but the corresponding shift on formation of $\left[\mathrm{WI}(\mathrm{CO})_{2}(\mathrm{dppm})\left\{\eta^{3}-\mathrm{C}_{9} \mathrm{H}_{7}(\mathrm{CN})_{4}\right\}\right]$ is only $24 \mathrm{~cm}^{-1}$. One possible rationalisation for these observations is that the formation of the tene adduct $\mathbf{3}$ from $\mathbf{2}$ is accompanied by isomerisation at the metal centre to a symmetrical ligand arrangement in which the iodide ligand is located trans to the $\mathrm{C}_{9} \mathrm{H}_{7}(\mathrm{CN})_{4}$ group (see Scheme 1). Such a structure is consistent with the NMR data and a trigonal twist process (which has been shown to operate in many complexes of the type $\left[\mathrm{MX}(\mathrm{CO})_{2} \mathrm{~L}_{2}^{\prime}\left(\eta^{3}\right.\right.$-allyl) $\left.][8,18]\right)$ provides a facile mechanism for isomerism. We suggest therefore that the $\mathrm{WI}(\mathrm{CO})_{2}\left(\mathrm{CNBu}^{i}\right)_{2}$ fragment can exhibit a flexible molecular geometry with the preferred structure dependent upon the identity of the $\eta^{3}$-bonded ligand. However, notwithstanding many attempts, we have been unable to obtain crystals of $\mathbf{3}$ suitable for X-ray characterisation, further to establish this hypothesis.

As predicted, the principal reaction type of the molybdenum complex $\left[\mathrm{MoBr}(\mathrm{CO})_{2}\left(\mathrm{CNBu}^{4}\right)_{2}\left(\eta^{3}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right]$ $\mathbf{1}$, was reversion to products with an $\eta^{7}$-bonded cyclo-
heptatrienyl ring by elimination of bromide and carbonyl ligands. The products of ligand elimination from complex 1 are markedly solvent dependent. Thus a short reflux of $\mathbf{1}$ in rigorously dried toluene resulted in loss of both carbonyl ligands and formation of $[\mathrm{MoBr}(-$ $\left.\mathrm{CNBu}^{1}\right)_{2}\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)$, 4. By contrast, in polar solvents such as acetone, elimination of bromide together with one carbonyl ligand to give $\left[\mathrm{Mo}(\mathrm{CO})\left(\mathrm{CNBu}^{t}\right)_{2}\left(\eta^{7}-\right.\right.$ $\left.\left.\mathrm{C}_{7} \mathrm{H}_{7}\right)\right] \mathrm{Br}$ is preferred and we have previously described the direct synthesis of $\left[\mathrm{Mo}(\mathrm{CO})\left(\mathrm{CNBu}^{t}\right)_{2}\left(\eta^{7}-\right.\right.$ $\left.\left.\mathrm{C}_{7} \mathrm{H}_{7}\right)\right]\left[\mathrm{PF}_{6}\right]$ from $\left[\operatorname{MoBr}(\mathrm{CO})_{2}\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right], \mathrm{CNBu}^{t}$ and $\left[\mathrm{NH}_{4}\right]\left[\mathrm{PF}_{6}\right]$ in refluxing acetone [10]. The formation of both 4 and $\left[\mathrm{Mo}(\mathrm{CO})\left(\mathrm{CNBu}^{i}\right)_{2}\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right]\left[\mathrm{PF}_{6}\right]$ can be described as associative ligand substitution processes which proceed via 1 in an $\eta^{7} \rightarrow \eta^{3} \rightarrow \eta^{7}$ pathway.
The syntheses of $\mathbf{1}$ and $\mathbf{2}$ from [MX(CO) $\left.)_{2}\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right]$ and two equivalents of $\mathrm{CNBu}^{t}$ contrasts with analogous reactions with $\mathrm{PR}_{3}\left[\mathrm{PR}_{3}=\mathrm{P}(\mathrm{OMe})_{3}\right.$ or $\left.\mathrm{PMe}_{3}\right]$ which proceed to give the carbonyl substituted products $\left[\mathrm{MX}(\mathrm{CO})\left(\mathrm{PR}_{3}\right)\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right] \quad$ or $\quad\left[\mathrm{M}(\mathrm{CO})\left(\mathrm{PR}_{3}\right)_{2}\left(\eta^{7}-\right.\right.$ $\left.\left.\mathrm{C}_{7} \mathrm{H}_{7}\right)\right]^{+}$directly with no evidence for $\eta^{3}-\mathrm{C}_{7} \mathrm{H}_{7}$ adducts as intermediates. Indeed in the case ( $\mathrm{M}=\mathrm{Mo}$, $\left.\mathrm{X}=\mathrm{Br}, \quad \mathrm{PR}_{3}=\mathrm{PMe}_{3}\right), \quad$ a cationic intermediate $\left[\mathrm{Mo}(\mathrm{CO})_{2}\left(\mathrm{PMe}_{3}\right)\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right] \mathrm{Br}$, formed by substitution of Br by $\mathrm{PMe}_{3}$, has been identified; subsequent warming to $80^{\circ} \mathrm{C}$ in toluene results in substitution of CO by the bromide counter anion to give [Mo-$\left.\operatorname{Br}(\mathrm{CO})\left(\mathrm{PMe}_{3}\right)\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right][13]$. In view of these findings

Table 3
Important bond lengths ( $\AA$ ) and angles ( ${ }^{\circ}$ ) for complex 2

| Bond lengths (Å) |  |  |  |
| :--- | :---: | :--- | ---: |

|  |  |  |  |

the possibility of the synthesis of an analogous $\mathrm{CNBu}^{t}$ complex was investigated. Reaction of [Mo-$\left.\operatorname{Br}(\mathrm{CO})_{2}\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right]$ with one equivalent of $\mathrm{CNBu}^{t}$ resulted in a red solution probably due to partial conversion to $\mathbf{1}$. However subsequent warming to $60^{\circ} \mathrm{C}$ gave a green solution from which the desired product, pale green, mono-substituted [Mo-$\left.\mathrm{Br}(\mathrm{CO})\left(\mathrm{CNBu}^{1}\right)\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right]$, 5, was isolated.

We have previously reported that, with the exception of $\left[\mathrm{Mo}(\mathrm{CO})\left(\mathrm{CNBu}^{\dagger}\right)_{2}\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right]\left[\mathrm{PF}_{6}\right]$, only dicarbonyl complexes of the type $\left[\operatorname{MoX}(\mathrm{CO})_{2}\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right]^{n+}$ ( $n=0, \mathrm{X}=$ one-electron ligand; $n=1, \mathrm{X}=$ two-electron ligand) undergo $\eta^{7} \rightarrow \eta^{3}$ hapticity conversion at the cycloheptatrienyl ring [11]. However, as a result of the similar donor/acceptor properties of the CO and $\mathrm{CNBu}^{t}$ ligands, it might be expected that the auxiliaries $\mathrm{Mo}(\mathrm{CO}) \mathrm{L}\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\left(\mathrm{L}=\mathrm{CO}\right.$ or $\left.\mathrm{CNBu}^{\prime}\right)$ would
confer closely related reactivity and therefore the possibility of $\eta^{7} \rightarrow \eta^{3}$ hapticity conversion in $\mathbf{5}$ was investigated. Complex 5, in solution in toluene, did not react with further $\mathrm{CNBu}^{t}$ at r.t. and although heating to $80^{\circ} \mathrm{C}$ resulted in substitution of CO by $\mathrm{CNBu}^{t}$ to give $\left[\mathrm{MoBr}\left(\mathrm{CNBu}^{1}\right)_{2}\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right]$, 4, there was no evidence for the intermediacy of an $\eta^{3}-\mathrm{C}_{7} \mathrm{H}_{7}$ bonded adduct. Treatment of an acetonitrile solution of 5 with $\mathrm{Ag}\left[\mathrm{BF}_{4}\right]$ resulted in bromide abstraction and formation of $\left[\mathrm{Mo}(\mathrm{CO})\left(\mathrm{CNBu}^{1}\right)(\mathrm{NCMe})\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right]\left[\mathrm{BF}_{4}\right]$, 6 . However, in contrast with the analogous reaction of $\left[\mathrm{MoI}(\mathrm{CO})_{2}\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right]$, which in acetonitrile affords $\left[\mathrm{Mo}(\mathrm{CO})_{2}(\mathrm{NCMe})_{3}\left(\eta^{3}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right]^{+}$as a mixture with $\left[\mathrm{Mo}(\mathrm{CO})_{2}(\mathrm{NCMe})\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right]^{+}$[9], complex 6 appears to be unreactive towards addition of further acetonitrile. These results further establish the requirement for the dicarbonyl $\mathrm{M}(\mathrm{CO})_{2}\left(\eta-\mathrm{C}_{7} \mathrm{H}_{7}\right)(\mathrm{M}=\mathrm{Mo}$ or W$)$ auxiliary in the design of complexes reactive towards $\eta^{7} \rightarrow \eta^{3}-\mathrm{C}_{7} \mathrm{H}_{7}$ hapticity conversion.

## 3. Experimental

### 3.1. General procedures

The preparation, purification and reactions of the complexes described were carried out under dry nitrogen. All solvents were dried by standard methods, distilled and deoxygenated before use. The compounds $\left[\mathrm{MoBr}(\mathrm{CO})_{2}\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right]$ and $\left[\mathrm{WI}(\mathrm{CO})_{2}\left(\eta^{7}-\right.\right.$ $\mathrm{C}_{7} \mathrm{H}_{7}$ )] were prepared by published procedures [19] and the chemicals $\mathrm{CNBu}^{t}$, tetracyanoethene and $\mathrm{Ag}\left[\mathrm{BF}_{4}\right]$ were supplied by Aldrich. $300 \mathrm{MHz}{ }^{1} \mathrm{H}-$ and $75 \mathrm{MHz}{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$-NMR spectra were recorded on Bruker AC 300 E or Varian Associates XL 300 spectrometers. IR spectra were obtained on a Perkin Elmer FT 1710 spectrometer and FAB mass spectra using a Kratos Concept 1S instrument. Microanalyses were by the staff of the Microanalytical Service of the Department of Chemistry, University of Manchester.

### 3.2. Preparation of $\left[\mathrm{MoBr}\left(\mathrm{CO}_{2}\left(\mathrm{CNBu}^{t}\right)_{2}\left(\eta^{3}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right] 1\right.$

A green solution of $\left[\mathrm{MoBr}(\mathrm{CO})_{2}\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right](0.495 \mathrm{~g}$, 1.53 mmol ) in toluene ( $50 \mathrm{~cm}^{3}$ ) was cooled to $0^{\circ} \mathrm{C}$ and then treated with $\mathrm{CNBu}^{t}(0.264 \mathrm{~g}, 3.18 \mathrm{mmol})$. After stirring for 30 min , the resulting red reaction mixture was evaporated to dryness and the residue recrystallised from diethylether $/ n$-hexane to give 1 as a red-brown solid; yield $0.353 \mathrm{~g}(47 \%)$. The redbrown tungsten derivative $\left[\mathrm{WI}(\mathrm{CO})_{2}\left(\mathrm{CNBu}^{t}\right)_{2}\left(\eta^{3}-\right.\right.$ $\mathrm{C}_{7} \mathrm{H}_{7}$ ) 2 was prepared in $73 \%$ yield starting from $\left[\mathrm{WI}(\mathrm{CO})_{2}\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right](0.866 \mathrm{~g}, 1.89 \mathrm{mmol})$ and $\mathrm{CNBu}^{t}$ $(0.331 \mathrm{~g}, 3.99 \mathrm{mmol})$ in toluene by a similar method except that the reaction was allowed to proceed at r.t. for 4.5 h .

Table 4
Crystal and data collection parameters for complex 2

| Crystal data |  |
| :---: | :---: |

& F_{\mathrm{o}}-F_{\mathrm{c}} .
\end{aligned}
$$

### 3.3. Preparation of $\left[\mathrm{WI}(\mathrm{CO})_{2}\left(\mathrm{CNBu}^{t}\right)_{2}\left\{\eta^{3}-\mathrm{C}_{9} \mathrm{H}_{7}(\mathrm{CN})_{4}\right\}\right]$ 3

Reaction of a solution of $\left[\mathrm{WI}(\mathrm{CO})_{2}\left(\mathrm{CNBu}^{1}\right)_{2}\left(\eta^{3}-\right.\right.$ $\left.\left.\mathrm{C}_{7} \mathrm{H}_{7}\right)\right](0.594 \mathrm{~g}, 0.95 \mathrm{mmol})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}\left(50 \mathrm{~cm}^{3}\right)$ with tetracyanoethene ( $0.123 \mathrm{~g}, 0.96 \mathrm{mmol}$ ) resulted in the rapid formation of a purple reaction mixture. After 2 h the solution was filtered, reduced in volume and $n$-hexane added to precipitate the crude product. Recrystallisation from $\mathrm{CH}_{2} \mathrm{Cl}_{2} / n$-hexane gave $\mathbf{3}$ as a deep purple solid; yield 0.433 g ( $61 \%$ ).

### 3.4. Preparation of $\left[\mathrm{MoBr}\left(\mathrm{CNBu}^{t}\right)_{2}\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right] \mathbf{4}$ from $\left[\mathrm{MoBr}(\mathrm{CO})_{2}\left(\mathrm{CNBu}^{t}\right)_{2}\left(\eta^{3}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right]$

A red solution of $\left[\operatorname{MoBr}(\mathrm{CO})_{2}\left(\mathrm{CNBu}^{7}\right)_{2}\left(\eta^{3}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right] \mathbf{1}$ $(0.270 \mathrm{~g}, 0.55 \mathrm{mmol})$ in toluene $\left(60 \mathrm{~cm}^{3}\right)$ was refluxed
for 30 min to give a green solution which was filtered, reduced in volume and treated with $n$-hexane to precipitate 4 as a green solid; yield $0.125 \mathrm{~g}(53 \%)$.

### 3.5. Preparation of $\left[\operatorname{MoBr}(\mathrm{CO})\left(\mathrm{CNBu}^{t}\right)\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right] 5$

A stirred solution of $\left[\operatorname{MoBr}(\mathrm{CO})_{2}\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right](0.335 \mathrm{~g}$, $1.04 \mathrm{mmol})$ in toluene $\left(60 \mathrm{~cm}^{3}\right)$ was treated with $\mathrm{CNBu}^{t}$ $(0.087 \mathrm{~g}, 1.05 \mathrm{mmol})$ resulting in a colour change from green to red. The reaction mixture was then warmed to $60^{\circ} \mathrm{C}$ and, over a period of 1 h , the colour of the solution reverted to green. The reaction mixture was then evaporated to dryness and the residue recrystallised from $\mathrm{CH}_{2} \mathrm{Cl}_{2} / n$-hexane to give $\mathbf{5}$ as a light green solid; yield $0.069 \mathrm{~g}(18 \%)$.

### 3.6. Preparation of <br> $\left[\mathrm{Mo}(\mathrm{CO})\left(\mathrm{CNBu}^{t}\right)(\mathrm{NCMe})\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right]\left[\mathrm{BF}_{4}\right] 6$

A stirred solution of $\left[\mathrm{MoBr}(\mathrm{CO})\left(\mathrm{CNBu}^{1}\right)\left(\eta^{7}-\mathrm{C}_{7} \mathrm{H}_{7}\right)\right] 5$ $(0.547 \mathrm{~g}, 1.45 \mathrm{mmol})$ in acetonitrile $\left(50 \mathrm{~cm}^{3}\right)$ was treated with $\mathrm{Ag}\left[\mathrm{BF}_{4}\right](0.283 \mathrm{~g}, 1.45 \mathrm{mmol})$ resulting in the rapid formation of a precipitate of AgBr . After 30 min , the reaction mixture was filtered to give a green solution which was then evaporated to dryness. Recrystallisation of the residue from $\mathrm{CH}_{2} \mathrm{Cl}_{2} / n$-hexane gave $\mathbf{6}$ as a green solid; yield $0.384 \mathrm{~g}(56 \%)$.

### 3.7. Crystal structure analysis of $\mathbf{2}$

The majority of details of the structure analysis carried out on 2 are presented in Table 4. Dark red crystals of 2 were obtained by slow diffusion of a hexane layer into a toluene solution of the compound. The structure was solved by Patterson methods and refined by full-matrix least-squares. Non-H atoms were refined anisotropically but the hydrogen atoms were included as a riding model with a fixed isotropic $U$. The crystallographic weighting scheme employed was $w^{-}$ $1=\sigma^{2}\left(F_{0}\right)+0.0005 F_{0}^{2}$. Neutral atom scattering factors were taken from reference [20] and all calculations were performed using the Nicolet SHELXTL [21] crystallographic software package.
