#### Abstract

The opening of a small ring in 3 -ferrocenyl-3-(1-naphthyl)cyclopropene (thermolysis, action of $\mathrm{HBF}_{4} \cdot \mathrm{Et}_{2} \mathrm{O}$ or $\mathrm{CF}_{3} \mathrm{SO}_{3} \mathrm{H}$ ), Z-2-bromo-1-ferrocenyl-1-(1-naphthyl)cyclopropane (action of $\mathrm{AlCl}_{3}$ ), and in 1-ferrocenyl-1-(1-naphthyl)cyclopropane (action of $\mathrm{Ph}_{3} \mathrm{C}^{+} \mathrm{BF}_{4}^{-}$) is accompanied by the alkylation of only the naphthalene fragment giving rise to 1 -ferrocenyl- $9 \mathrm{~b} H$-benzo[e]indene or 1-ferrocenyl- 3 H -benzo[e]indene. This is connected with a 'non-bisecting' position of the naphthalene fragment relative to the three-membered cycle in the starting compounds. The compound 1 -ferrocenyl- $9 \mathrm{~b} H$-benzo[e]indene gives [ $4+2]$-cycloadducts with $N$-phenyl(azodicarboximide) and $N$-phenylmaleimide. X-ray structural data are presented for 3 -ferrocenyl-3-(1-naphthyl)cyclopropene and its adduct with 1,3-diphenylisobenzofuran, $Z$-2-bromo-1-ferrocenyl-1-(1-naphthyl)cyclopropane, and 1 -fer-rocenyl-1-(1-naphthyl)cyclopropane. © 1998 Elsevier Science S.A. ## 1. Introduction

The introduction of a ferrocenyl substituent in position 3 of the cyclopropene ring significantly changes the properties of the latter. Some well known examples of changes in the reaction properties of the small carbocycle include the transformations of 1,2,3-triferrocenylcyclopropene [1], 3-ferrocenyl-3-phenylcyclopropene 1 [2-4] and also of 3-tert-butyl- and 3-adamantyl-3-ferrocenylcyclopropenes 2a,b [5]. In particular, 3-para-tolyl-1,2,3triferrocenylcyclopropene, even at $0^{\circ} \mathrm{C}$, in a solution of $\mathrm{CHCl}_{3}$, rearranges due to cleavage of the small ring, followed by cyclization at the ferrocenyl and aryl frag-

[^0]ments [1]. The compound 3-ferrocenyl-3-phenylcyclopropene 1 at acid or thermal cleavage of the small ring forms 3-ferrocenylindene 2 [2-4].

In our opinion, the high regioselective intramolecular alkylation of the phenyl substituent and not of the ferrocenyl one, as normally observed for other ferrocenyl compounds $[1,6-8]$, should be related to the spatial
structure of the cyclopropene compound 1 [4]. According to X-ray analysis data, the phenyl subsituent has a 'non-bisecting' position relative to the small ring, while the ferrocenyl fragment has a 'bisecting' spatial orientation. Therefore, during the small ring cleavage, the alkylation should take place at the substituent which has a 'non-bisecting' orientation. However, if the ferrocenyl substituent occupies a 'non-bisecting' position one should expect that the alkylation will take place at the ferrocenyl fragment. In the reaction of 3 -alkyl-3-ferrocenylcyclopropenes 3a,b (the ferrocenyl fragment has a 'non-bisecting' position) with 1,3-diphenylisobenzofuran, the adduct $\mathbf{5 a}, \mathbf{b}$ is formed from the intermediate 3 -alkyl-1,2-(1-propene-1,3-diyl)ferrocene $\mathbf{4 a , b}$ [5].

Monocrystals of compounds 6,7, and 9 necessary for X-ray structural analysis were obtained by crystallization from hexane. General views of these molecules are shown in Fig. 1(Fig. 2a) and Fig. 3, respectively. The X-ray analysis data indicate that all studied compounds (cyclopropene 6, monobromide 7 and cyclopropane 9) have identical conformations. This is probably caused by sterical restrictions imposed on the rotation of the geminal ferrocenyl and aryl substituents arround the simple $\mathrm{C}-\mathrm{C}$ bonds.
The principal elements in the structures of $\mathbf{6}, 7$, and 9 are the three-membered rings. The three-membered ring in compound $\mathbf{6}$ is a triangle with an acute angle

The idea that regioselectivity in similar reactions depends on the spatial orientation of the substituents (the conformational structure of the molecules) is not studied in detail and deserves further investigation.

## 2. Results and discussion

In a continuation of our investigations, we synthesized crystalline 3 -ferrocenyl-3-(1-naphthyl)cyclopropene 6, Z-2-bromo-1-ferrocenyl-1-(1-naphthyl)cyclopropane 7, and 1-ferrocenyl-1-(1-naphthyl)cyclopropane 9 starting from 2,2-dibromo-1-ferrocenyl-1-(1-naphthyl)cyclopropane 8 and studied their structures and some of their chemical transformations.
extended towards $\mathrm{C}(11)$. The length of the $\mathrm{CH}=\mathrm{CH}$ double bond ( $d=1.272(6) \AA$ ) and the angle $\omega$ at $\mathrm{C}(11)$ is equal to $50.0(2)^{\circ}$. In compounds 7 and 9 , the angles at the carbon atoms $\mathrm{C}(1)$ and $\mathrm{C}(21)$, respectively, are smaller than $60^{\circ}\left(56.4\right.$ and $\left.59.0^{\circ}\right), C(2)-C(3)$ and $C(22)-$ $\mathrm{C}(23)$ bond lengths are shorter than the lengths of the lateral bonds $C(1)-C(2), C(1)-C(3), C(21)-C(22)$, and $C(21)-C(23)$. The angles of rotation of the ferrocene and naphthalene fragments in the molecules under consideration correspond to the 'bisecting' position of the former and 'non-bisecting' position of the latter relative to the small ring (Figs. 1, 2a and 3). X-ray analysis of monobromide 7 revealed that the unit cell of monoclinic

crystals of this compound contains two molecules with the bromine atoms close to each other (Fig. 2b). In all the three compounds $\mathbf{6}, 7$, and $\mathbf{9}$, the $\mathrm{Fe}-\mathrm{C}$ and $\mathrm{C}-\mathrm{C}$ bonds as well as the geometry of the ferrocene sandwich have normal parameters.

thalene and ferrocene fragments in the adduct $\mathbf{1 1}$ (Fig. 4).

Not only was the adduct $\mathbf{1 1}$ isolated from the reaction mixture but also Z-1-ferrocenyl-1-(1-naph-thyl)propene-1. The fact that propene 12a is formed in the reaction of $\mathbf{6}$ with $\mathbf{1 0}$ points to a possible opening of the small ring in the thermal process. When the reaction was carried out at a higher temperature (in boiling $m$-xylene), the yields of both the adduct $\mathbf{1 1}$ and propene

${ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C}$-NMR spectra of the adduct $\mathbf{1 1}$ correspond to only one structural isomer, which attests to a stereospecific $[4+2]$-cycloaddition. The structure of compound $\mathbf{1 1}$ is established on the basis of X-ray data. General view of this molecule is shown in Fig. 4. X-ray data show that compound $\mathbf{1 1}$ has the structure of exo-3-ferrocenyl-3-(1-naphthyl)-1,5-diphenyl-6,7-benzo8 -oxatricyclo[3.2.1.0 ${ }^{2,4}$ ]oct-6-ene with a syn-orientation of the naphthalene substituent. The non-equivalence of the hydrogen atoms $\mathrm{H}(2)$ and $\mathrm{H}(4)$ in the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum and of the carbon atoms $C(1)$ and $C(5)$ in the ${ }^{13} \mathrm{C}-\mathrm{NMR}$ spectrum (see Section 4) can easily be explained by a mutual 'anti'-orientation of the naph-

A product isolated from the reaction mixture was identified as 1 -ferrocenyl- $9 \mathrm{~b} H$-benzo[e]indene $\mathbf{1 3}$ on the basis of ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectral data [ $\delta$ $2.49(\mathrm{~s}, 1 \mathrm{H}, \mathrm{CH}), 6.48(\mathrm{~d}, 1 \mathrm{H}, J=5.55 \mathrm{~Hz}), 6.80(\mathrm{~d}, 1$ $\mathrm{H}, J=5.55 \mathrm{~Hz}$ ), plus signals for 9 H of ferrocene and 6 H of naphthalene fragments].

The structures of the adducts $\mathbf{1 4}$ and $\mathbf{1 5}$ were established on the basis of ${ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C}$-NMR spectral data (see Section 4). The fact that the signals for the protons of the $\mathrm{C}_{5} \mathrm{H}_{4}$ group of the ferrocene fragment are shifted downfield relative to the singlet for the protons of the non-substituted cyclopentadienyl ring of ferrocene made it possible to attribute $\mathbf{1 5}$ to the exo-type structure [2,6].

It has also been discovered that the three-membered ring in cyclopropene 6 undergoes smooth opening under the action of $\mathrm{HBF}_{4} \cdot \mathrm{Et}_{2} \mathrm{O}$. Following treatment of the reaction mixture with $N, N$-dimethylaniline, $Z$ - and $E$-1-ferrocenyl-1-(1-naphthyl)prop-1-enes 12a and 12b (ca. 5:1, ${ }^{1} \mathrm{H}$-NMR data), 1 -ferrocenyl-3 H -benzo[e]indene $\mathbf{1 6}$, and $Z$ - and $E$-3-( $p$-dimethylaminophenyl)-1-ferrocenyl-1-(1-naphthyl)prop-1-enes 17a and 17b (ca. 4:1, ${ }^{1} \mathrm{H}$ NMR data) were isolated by TLC.

The opening of a small ring in cyclopropene 6 with superacid $\mathrm{CF}_{3} \mathrm{SO}_{3} \mathrm{H}$ gave mainly benzoindene 16 (ca. $64 \%$ ) and the products of $p$-alkylation of $N, N$-dimethylaniline, 17a,b (ca. 11\%).
It is believed that in this case the protonation of cyclopropene 6 results in an intermediate cyclopropyl cation 18, which undergoes smooth opening to give a ferrocenylallylic cation 19 [2-4] stabilized by the ferrocene substituent.

Selected bond lengths ( $\AA$ ): $\mathrm{C}_{11}-\mathrm{C}_{12}=1.519(6) ; \mathrm{C}_{11}-\mathrm{C}_{13}=1.532(6) ; \mathrm{C}_{12}-\mathrm{C}_{13}=1.513(6)$; and selected bond angles ( ${ }^{\circ}$ : $\mathrm{C}_{12}-\mathrm{C}_{11}-\mathrm{C}_{13}=59.5(3) ; \mathrm{C}_{13}-\mathrm{C}_{12}-\mathrm{C}_{11}=60.7(3) ; \mathrm{C}_{12}-\mathrm{C}_{13}-\mathrm{C}_{11}=59.8(3) ; \mathrm{C}_{34}-\mathrm{C}_{11}-\mathrm{C}_{10}=113.9(4) ; \mathrm{C}_{34}-\mathrm{C}_{11}-\mathrm{C}_{12}=121.7(4) ; \mathrm{C}_{34}-\mathrm{C}_{11}-\mathrm{C}_{13}=$ 125.7(4).

The cation 19 then enters into intramolecular transformations and alkylates the naphthalene ('non-bisecting') substituent, it also alkylates $\mathrm{N}, \mathrm{N}$-dimethylaniline by the less substituted carbenium center [ 9,10 ], and undergoes reduction. Reduction of this type of ferrocenylallylic cations has previously been observed for 1 -ferrocenyl-1-phenylallyl cation [4] and 3-ferrocenyl-methylene-1,2,7,7-tetramethylbicyclo[2.2.1]hept-2-yl cation [11,12], which is associated, in our opinion, with the participation of the iron atom [13].

The formation of compounds 12a and 13 in thermal processes might occur due to heterolysis of one of the $\sigma$-bonds of the small ring $[3,5]$. The intermediate carbenoid $\mathbf{2 0}$ is involved in intramolecular alkylation and reduction analogous to those of the ferrocenylallylic cation 19.

However, the reduction of 20, unlike that of cation 19, is stereospecific, this results in the $Z$-alkene 12a; the intramolecular transformation of 20 gives $9 \mathrm{~b} H$-benzo[e]indene 13, which differs in structure from 3 H -benzo[e]indene 16.
It has also been demonstrated that the small ring is easily opened upon treatment of monobromocyclopropane 7 with $\mathrm{AlCl}_{3}$ [4] and of cyclopropane 9 with triphenylcarbenium tetrafluoroborate [14,15].
The opening of a small ring in 7 occurs as a result of detachment of a halide anion and generation of a cationic center in the cyclopropane ring with subsequent (or simultaneous) opening of the small ring and formation of an allylic cation 19.

Thus, 1-ferrocenyl-3H-benzo[e]indene 16 was isolated as the main reaction product (ca. $67 \%$ ). The reaction of cyclopropane 9 with triphenylcarbenium tetrafluoroborate occurs in a more complex way. Ring-opening in 9 due to hydride detachment $[14,15]$ and the formation of the allylic cation 19 is only one of the processes that occur:

$$
7 \xrightarrow[-\mathrm{Ph}_{3} \mathrm{CH}]{+\mathrm{Ph}_{3} \mathrm{C}+\mathrm{BF}_{4}}[\mathbf{1 8}] \rightarrow[\mathbf{1 9}] \xrightarrow{\mathrm{PhN}^{\left(C H_{3}\right)}} \mathbf{1 6}(23 \%)+\mathbf{1 7 a , b}(5 \%)
$$

In addition, competitive opening of the three-membered ring occurs predominantly due to electrophilic addition of $\mathrm{Ph}_{3} \mathrm{C}^{+}$leading to cation 21. Its deprotonation with $N, N$-dimethylaniline results in 1 -ferrocenyl-4,4,4-triphenyl-1-(1-naphthyl)but-1-ene 22 as a mixture of two isomers 22a and 22b in a ratio of ca. 2:1 according to ${ }^{1} \mathrm{H}-\mathrm{NMR}$ data.

## 4. Experimental

The solvents were dried by standard methods and distilled prior to use. Column chromatography was carried out on $\mathrm{Al}_{2} \mathrm{O}_{3}$ (activity III according to Brockmann). Elemental analyses were carried out by the Microanalytical laboratory of the Department of Chemistry of the Moscow State University. ${ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C}$-NMR spectra were registered in $\mathrm{CDCl}_{3}$ on a Gemini 200 Varian spectrometer at 200 and 50 MHz using $\mathrm{Me}_{4} \mathrm{Si}$ as the internal standard. The parameters of the unit cell and the X-ray diffraction intensities were recorded on Siemens P4/PC (compounds 6, 9 and 11) and Siemens P4 (compound 7) spectrometers (Table 1).

The major isomer 22a was isolated individually. However, the configuration of compounds 22a and 22b ( $Z$ - or $-E$ ) has not been established yet.

## 3. Conclusion

Thus, the results of this study support our previous conclusion [4] that the regioselectivity of intramolecular transformations of 3-aryl-3-ferrocenylcyclopropenes $\mathbf{1}$ and 6 and 1-aryl-1-ferrocenylcyclopropanes 7 and 9 is determined by spatial orientation of substituents in the starting compounds. Aryl substituents that occupy a 'non-bisecting' position relative to the three-membered ring undergo alkylation upon opening of the small ring under various conditions. We did not observe intramolecular cyclization involving the ferrocene fragment, although such an intramolecular alkylation of a $\gamma$-ferrocenyl group (relative to the cationic or carbenoid center) is well known. This seems to be connected with the 'bisecting' orientation of the ferrocene fragment in compounds under study.

Indene 16, $(0.027 \mathrm{~g}, 15 \%), R_{\mathrm{f}} 0.35$, yellow crystals, m.p. $136-137^{\circ} \mathrm{C} .{ }^{1} \mathrm{H}-\mathrm{NMR}: \delta 3.85$ (dd, $2 \mathrm{H}, \quad J=1.2$, $6.92 \mathrm{~Hz}), 4.09\left(\mathrm{~s}, 5 \mathrm{H}, \mathrm{C}_{5} \mathrm{H}_{5}\right), 3.72(\mathrm{~m}, 1 \mathrm{H}), 4.08(\mathrm{~m}$, $1 \mathrm{H}), 4.25(\mathrm{~m}, 1 \mathrm{H}), 4.52(\mathrm{~m}, 1 \mathrm{H})\left(\mathrm{C}_{5} \mathrm{H}_{4}\right), 6.43(\mathrm{t}, 1 \mathrm{H}$, $J=6.95 \mathrm{~Hz}), 7.15-7.60,7.75-7.93\left(\mathrm{~m}, 6 \mathrm{H}, \mathrm{C}_{10} \mathrm{H}_{6}\right)$.

Anal. Found: C, 78.93, H, 4.98, Fe, 15.72. $\mathrm{C}_{23} \mathrm{H}_{18} \mathrm{Fe}$. Calc.: C, 78.87; H, 5.18; Fe, 15.95\%.

### 4.10. Reaction of cyclopropene 6 with $\mathrm{CF}_{3} \mathrm{SO}_{3} \mathrm{H}$

Trifluoromethanesulfonic acid $(0.5 \mathrm{ml})$ was added to a solution of $6(0.175 \mathrm{~g})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(20 \mathrm{ml})$. The mixture was stirred for 30 min at $20^{\circ} \mathrm{C}$ under dry argon and then $N, N$-dimethylaniline ( 0.5 ml ) was added. Following conventional work-up and TLC on silica gel, compounds $\mathbf{1 7 a}, \mathrm{b}(0.026 \mathrm{~g}, 11 \%), R_{\mathrm{f}} 0.42$, and $16(0.112 \mathrm{~g}, 64 \%), R_{\mathrm{f}} 0.36$, m.p. $137^{\circ} \mathrm{C}$, were obtained.

### 4.11. Opening of a small ring in monobromide 7

Aluminum chloride $(0.1 \mathrm{~g})$ was added to a solution of monobromocyclopropane $7(0.22 \mathrm{~g}, 0.5 \mathrm{mmol})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(50 \mathrm{ml})$. The mixture was stirred for 2 h at $20^{\circ} \mathrm{C}$ under dry argon and then $\mathrm{N}, \mathrm{N}$-dimethylaniline $(1 \mathrm{ml})$ was added. The organic layer was separated and washed with $1 \% \mathrm{HCl}$ and water. Following removal of the solvent and TLC on silica gel, indene $\mathbf{1 6}$ $(0.13 \mathrm{~g}, 68 \%), R_{\mathrm{f}} 0.35$, m.p. $136-137^{\circ} \mathrm{C}$, was obtained.

### 4.12. Reaction of cyclopropane $\mathbf{9}$ with triphenylmethylium tetrafluoroborate

Triphenylmethylium tetrafluoroborate $(0.4 \mathrm{~g})$ was added to a solution of cyclopropane $9(0.35 \mathrm{~g}, 1$ $\mathrm{mmol})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(50 \mathrm{ml})$ at $20^{\circ} \mathrm{C}$ under dry argon. The mixture was stirred for 2 h and then worked up as described above. Following TLC on silica gel (hex-ane-benzene, $2: 1$ ), the following products were isolated: $\mathbf{1 7 a}, \mathbf{b}(0.025 \mathrm{~g}, 5 \%), R_{\mathrm{f}} 0.43$; indene $16(0.081 \mathrm{~g}$, $23 \%), R_{\mathrm{f}} 0.36$, m.p. $136-137^{\circ} \mathrm{C}$; and a mixture of two isomeric butenes 21a and 21b (ca. 2:1), $R_{\mathrm{f}} 0.27$, yellow powder, m.p. $186-188^{\circ} \mathrm{C}$. Anal. Found: C, $85.11, \mathrm{H}$, 5.49, Fe, 9.68. $\mathrm{C}_{42} \mathrm{H}_{34} \mathrm{Fe}$. Calc.: C, 84.84; H, 5.76; Fe, $9.40 \%$. Recrystallization from benzene afforded the individual isomer 22a, m.p. $213-214^{\circ} \mathrm{C}$. ${ }^{1} \mathrm{H}-\mathrm{NMR}: ~ \delta$ $3.56(\mathrm{~d}, 2 \mathrm{H}, J=5.28 \mathrm{~Hz}), 4.19\left(\mathrm{~s}, 5 \mathrm{H}, \mathrm{C}_{5} \mathrm{H}_{5}\right), 3.89(\mathrm{~m}$, $1 \mathrm{H}), 3.98(\mathrm{~m}, 1 \mathrm{H}), 4.26(\mathrm{~m}, 1 \mathrm{H}), 4.81(\mathrm{~m}, 1 \mathrm{H})\left(\mathrm{C}_{5} \mathrm{H}_{4}\right)$, $6.93(\mathrm{t}, 1 \mathrm{H}, J=5.3 \mathrm{~Hz}), 7.01-8.20(\mathrm{~m}, 22 \mathrm{H}$, arom.). Anal. Found: C, 84.72; H, 5.89; Fe, 9.21. Isomer 22b, ${ }^{1} \mathrm{H}-\mathrm{NMR}: \delta 3.50(\mathrm{~d}, 2 \mathrm{H}, J=5.4 \mathrm{~Hz}), 3.87(\mathrm{~s}, 5 \mathrm{H}$, $\mathrm{C}_{5} \mathrm{H}_{5}$ ), $3.43(\mathrm{~m}, 1 \mathrm{H}), 3.75(\mathrm{~m}, 1 \mathrm{H}), 3.99(\mathrm{~m}, 2 \mathrm{H})$ $\left(\mathrm{C}_{5} \mathrm{H}_{4}\right), 6.92(\mathrm{t}, 1 \mathrm{H}, J=5.4 \mathrm{~Hz}), 7.10-8.20(\mathrm{~m}, 22 \mathrm{H}$, arom.).
