Abstract

Treatment of the complex Mo(Nmes)Cl₂(PMe₃)₃ (1) (mes = 2,4,6-Me₃C₆H₂, 2,4,6-trimethylphenyl) with two equivalents of the potassium salt of methyl xanthate, KS₂COMe, or the potassium 1-pyrrole-carbodithioate, KS₂C(NC₄H₄), gave Mo(Nmes)(S-S)₂(PMe₃) (S-S = S₂COMe **2**; S₂C(NC₄H₄) **3**). When the reaction of **1** with KS₂COMe is carried out in a 1:1 stoichiometry, the complex Mo(Nmes)(S₂COMe)Cl(PMe₃)₂ (**4**) is obtained. The chlorine atom in **4** occupies the *trans* position with respect to the organoimido ligand. MO calculations of the EH type rationalize the preferential formation of **4** as the thermodynamically preferred isomer in this metathesis reaction. The reaction of **4** with CO produces Mo(Nmes)(S₂COMe)Cl(CO)(PMe₃) (**5**). Reaction of **1** with carbon disulfide yields the complex Mo(Nmes)Cl₂(S₂CPMe₃) (**6**), containing a trihapto-(*S*,*S'*,*C*) phosphoniumdithiocarboxylate ligand. © 1999 Elsevier Science S.A. Keywords: Imido; Molybdenum; Dithio-ligand; EHMO calculations

1. Introduction

Interest in the chemistry of compounds containing organoimido ligands has increased enormously in the last two decades. In particular, the use of this ligand in stabilizing transition metals in high oxidation states [1] and the role they play in the development of welldefined catalysts are well documented [2].

Previous work from our laboratories has resulted in the preparation of a variety of oxo- and imido-derivatives of molybdenum containing dithioacid and related ligands [3,4]. As an extension of this work [5], we now wish to report the synthesis and characterization of some new d²-imido complexes of molybdenum containing xanthate, dithiocarbamate and phosphoniumdithiocarboxylate ligands. As discussed below, they have been prepared using the complex Mo(Nmes)Cl₂(PMe₃)₃ (1) (mes = 2,4,6-trimethylphenyl, Me₃C₆H₂) as the starting material. A molecular orbital (MO) rationalization of the preferential formation of only one isomer of the complex $Mo(Nmes)(S_2COMe)Cl(PMe_3)_2$ (4) is also presented.

2. Experimental

Microanalyses were carried out by the Microanalytical Service of the University of Sevilla. IR spectra were recorded on a Perkin–Elmer model 883 spectrophotometer. ¹H-, ¹³C- and ³¹P-NMR spectra were run on Bruker AMX-300 and AMX-500 spectrometers. ³¹P shifts were measured with respect to external 85% H_3PO_4 . ¹³C-NMR spectra were referenced using the ¹³C resonance of the solvent as an internal standard but are reported with respect to SiMe₄. All preparations and other operations were carried out under oxygen-free nitrogen, following conventional Schlenk techniques. Solvents were dried and degassed before use. The light petroleum ether used had b.p. 40–60°C. The compound

E-mail address: galindo@cica.es (A. Galindo)

 $Mo(Nmes)Cl_2(PMe_3)_3$ was prepared according to the literature procedure [5].

2.1. Preparation of $Mo(Nmes)(S_2COMe)_2(PMe_3)$ (2)

A mixture of Mo(Nmes)Cl₂(PMe₃)₃ (0.07 g, 0.15 mmol) and KS₂COMe (0.04 g, 0.30 mmol) was dissolved in THF (25 ml). The suspension was refluxed overnight, the solvent was removed by pumping under vacuum and the resulting residue extracted with light petroleum. The solution was concentrated and cooled to -20° C. Compound 2 was isolated as an orangebrownish solid in 30% yield. ³¹P{¹H}-NMR (C₆D₆): δ -4.1 (s). ¹H-NMR (C₆D₆): δ 6.44 (s, 2H, CH, Ph), 3.47, 3.43 (s, 3H, OCH₃), 2.33 (s, 6H, o-CH₃), 1.91 (s, 3H, p-CH₃), 1.17 (d, $J_{HP} = 8.6$ Hz, 9H, PMe₃). $^{13}C{^{1}H}$ -NMR (125 MHz, C_6D_6): δ 218.4 (s, S_2C), 172.2 (s, S₂C), 153.7 (s, ipso-C), 135.4, 135.3 (s, p-C and o-C), 128.7 (s, m-C), 57.4, 57.0 (s, OCH₃), 20.8 (s, p-CH₃), 19.7 (s, o-CH₃), 15.1 (d, $J_{CP} = 26.7$ Hz, PMe₃). Crystals of complex 2 were contaminated by small amounts of 4. This makes it difficult to obtain reliable microanalytical data. Anal. Calc. for C₁₆H₂₆NMoO₂PS₄: C, 37.0; H, 5.0; N, 2.7. Found: C, 38.5; H, 5.3; N, 2.7%.

2.2. Preparation of $Mo(Nmes)[S_2C(NC_4H_4)]_2(PMe_3)$ (3)

To a solution of Mo(Nmes)Cl₂(PMe₃)₃ (0.12 g, 0.23 mmol) in THF (15 ml) was added KS₂C(NC₄H₄) (0.09 g, 0.46 mmol) in THF (15 ml). The mixture was stirred overnight at room temperature (r.t.). The solvent was then removed and the residue extracted with ether/light petroleum. Concentration of the solution and cooling at -20° C gave orange crystals of compound 3 in 50% yield. ${}^{31}P{}^{1}H$ -NMR (C₆D₆): δ - 8.33 (s). ${}^{1}H$ -NMR (300 MHz, C₆D₆): δ 7.63, 7.52 (t, ${}^{3}J_{HH} = 2.3$ Hz, 2H, NC₄ H_4), 6.33 (s, 2H, CH, Ph), 6.01, 5.96 (t, ${}^{3}J_{HH} = 2.3$ Hz, 2H, NC_4H_4), 1.96 (s, 6H, *o*-CH₃), 1.84 (s, 3H, p-C H_3), 1.02 (d, $J_{\rm HP} = 9.2$ Hz, 9H, PMe₃). ¹³C{¹H}-NMR (75 MHz, C_6D_6): δ 206.7 (d, $J_{CP} = 4.3$ Hz, eq-S₂C), 187.3 (s, ax-S₂C), 153.3 (s, ipso-C), 136.4, 135.4 (s, p-C and o-C), 128.4 (s, m-C), 121.2, 118.5, 114.3, 109.2 (s, NC₄H₄), 20.7 (s, p-CH₃), 19.3 (s, o-CH₃), 14.7 (d, $J_{CP} = 26.2$ Hz, PMe₃). Anal. Calc. for C₂₂H₂₈N₃MoPS₄: C, 44.8; H, 4.4; N, 7.1. Found: C, 44.7; H, 4.4; N, 7.0%.

2.3. Preparation of $Mo(Nmes)(S_2COMe)Cl(PMe_3)_2$ (4)

A mixture of Mo(Nmes)Cl₂(PMe₃)₃ (0.26 g, 0.49 mmol) and KS₂COMe (0.07 g, 0.5 mmol) was dissolved in THF (25 ml). The solution was stirred for 24 h at r.t. The solvent was removed and the dark red solid was recrystallized from ether/light petroleum to give **4** as red crystals in 55% yield. ³¹P{¹H}-NMR (C₆D₆): δ 0.3

(s). ¹H-NMR (500 MHz, C_6D_6): δ 6.49 (s, 2H, *CH*, Ph), 3.71 (s, 3H, OCH₃), 2.44 (s, 6H, *o*-CH₃), 1.94 (s, 3H, *p*-CH₃), 1.37 (d, $J_{HP} = 7.7$ Hz, 18H, PMe₃). ¹³C{¹H}-NMR (125 MHz, C_6D_6): δ 235.4 (s, S_2C), 150.8 (s, *ipso*-C), 135.7, 134.7 (s, *p*-C and *o*-C), 128.8 (s, *m*-C), 57.9 (s, OCH₃), 19.7 (s, *p*-CH₃), 19.1 (m, PMe₃), 18.3 (s, *o*-CH₃). Anal. Calc. for $C_{17}H_{32}NCIMoOP_2S_2$: C, 39.0; H, 6.1; N, 2.7. Found: C, 39.0; H, 6.3; N, 2.7%.

2.4. Interaction of **4** with CO: synthesis of $Mo(Nmes)(S_2COMe)Cl(CO)(PMe_3)$ (**5**)

A solution of Mo(Nmes)(S₂COMe)Cl(PMe₃)₃ (0.06 g, 0.11 mmol) in Et₂O (20 ml) was pressurized with CO (2 atm) in a pressure bottle. The mixture was stirred overnight and then the solvent was removed under vacuum. Crystallization of the residue always gave a mixture of the starting material 4 and compound 5. The separation by fractional crystallization was not possible, but 5 was fully characterized by solution NMR. ${}^{31}P{}^{1}H{}-NMR$ (C₆D₆): δ - 5.65 (s). ¹H-NMR (500 MHz, C_6D_6): δ 6.38 (s, 2H, CH, Ph), 3.54 (s, 3H, OCH₃), 2.31 (s, 6H, o-CH₃), 1.90 (s, 3H, p-CH₃), 1.22 (d, $J_{\rm HP} = 8.9$ Hz, 9H, PMe₃). ¹³C{¹H}-NMR (125) MHz, C_6D_6): δ 238.6 (d, $J_{CP} = 7.6$ Hz, CO), 235.8 (s, S₂C), 150.1 (s, *ipso*-C), 136.9, 136.7 (s, *p*-C and *o*-C), 129.0 (s, m-C), 58.2 (s, OCH₃), 20.8 (s, p-CH₃), 19.1 (s, o-CH₃), 16.5 (d, $J_{CP} = 27.5$ Hz, PMe₃).

2.5. Preparation of $Mo(Nmes)Cl_2(S_2CPMe_3)$ (6)

A solution of Mo(Nmes)Cl₂(PMe₃)₃ (0.20 g, 0.38 mmol) in THF (20 ml) was treated with one equivalent of CS_2 (0.38 ml of a solution 1 M in THF). The mixture was stirred overnight at r.t. and an orange solid was formed. The resulting suspension was filtered, the solution evaporated to dryness and the residue extracted with THF. Concentration and cooling at -30° C afforded orange crystals of 6. ³¹P{¹H}-NMR (acetone d_6): δ 42.5 (s). ¹H-NMR (500 MHz, acetone- d_6): δ 6.80 (s, 2H, CH, Ph), 2.36 (s, 6H, o-CH₃), 2.20 (s, 3H, p-C H_3), 1.94 (d, $J_{\rm HP} = 13.8$ Hz, 9H, PMe₃). ¹³C{¹H}-NMR (125 MHz, acetone-*d*₆): δ 153.6 (s, *ipso*-C), 139.5, 136.6 (s, p-C and o-C), 129.7 (s, m-C), 97.5 (d, $J_{CP} =$ 78.2 Hz, CS₂), 21.3 (s, p-CH₃), 18.6 (s, o-CH₃), 11.2 (d, $J_{\rm CP} = 57.2$ Hz, PMe_3). Anal. Calc. for $C_{13}H_{20}NCl_2MoPS_2 \cdot \frac{1}{4}THF$: C, 35.7; H, 4.7; N, 3.0. Found: C, 35.3; H, 5.0; N, 2.9%.

2.6. Extended Hückel molecular orbital study

The relative stability of the three isomers (I-III) of complex Mo(Nmes)(S₂COMe)Cl(PMe₃)₂ (4) was studied employing the model compounds Mo(NH)(S₂COH)Cl(PH₃)₂ at the extended Hückel level [6] by using a weighted modified Wolfsberg-Helmholz

formula [7]. The calculations were performed by means of the CACAO package [8]. The STO parameters used are the standard ones tabulated in the program. The geometry of the model compounds was based on the ideal octahedron and bond distances and angles were adapted from the results on a structural search of the Cambridge Crystallographic Database [9].

3. Results and discussion

We have recently reported [5] that treatment of compound Mo(Nmes)Cl₃(dme) with two equivalents of PMe₃ and subsequent Na-Hg reduction, in the presence of one additional equivalent of PMe₃, gives Mo(Nmes)Cl₂(PMe₃)₃ (1). This synthetic methodology provides easy access to the chemistry of the d^2 -Mo(Nmes) moiety. We also showed that interaction of 1 with two Mo(Nmes)equivalents of KS₂CO^{*i*}Pr gave $(S_2CO'Pr)_2(PMe_3)$, in contrast with the behavior previously observed for the oxo-analogue of 1, which under similar conditions gave MoO[S₂C(PMe₃)OⁱPr](S₂COⁱPr) [3b]. With the aim of ascertaining if the attainment of the classical six-coordinate structure is a general observation, we have enlarged the number of d^2 -imido derivatives of molybdenum by preparing the complexes $Mo(Nmes)(S_2COMe)_2(PMe_3)$ (2) and Mo(Nmes)- $[S_2C(NC_4H_4)]_2(PMe_3)$ (3). They can be synthesized by reacting 1 with the potassium salts of methyl xanthate and 1-pyrrole-carbodithioate, respectively (Eq. (1)), and are obtained as orange-brownish and orange crystalline solids, respectively.

Both compounds are moderately stable upon exposure to air in the solid state. Their NMR spectra are consistent with the schematic structure shown in Eq. (1). The PMe₃ ligand of compounds **2** and **3** gives a ³¹P{¹H}-NMR singlet, with a chemical shift characteristic of coordinated PMe₃ ligands. The two dithio-ligands give rise to two different sets of signals. For instance, two resonances are observed for the S₂C carbon atoms of **3** in the ¹³C{¹H}-NMR spectra (206.7 (d, $J_{CP} = 4.3$ Hz, S₂C eq) and 187.3 (s, S₂C ax) ppm). These resonances are in the range expected for bidentate dithio-ligands.

The formation of **2** requires heating for completion. When the reaction is carried out at r.t., the analysis of the reaction mixture by ${}^{31}P{}^{1}H$ -NMR reveals three species: the starting material **1**, complex **2** and a singlet resonance corresponding to a new compound. This complex was identified as the monosubstituted xanthate derivative Mo(Nmes)(S₂COMe)Cl(PMe₃)₂, (**4**), which is best prepared by carrying out the reaction of **1** and

 KS_2COMe in a 1:1 ratio, at r.t. If the substitution of one chloride and one PMe₃ groups by the xanthate, occurs without ligand redistribution, three possible isomers (I–III) can be envisaged.

The imido ligand exerts a strong *trans* influence [1b,10]. By assuming that the *trans* effect follows the same trend of the *trans* influence, one would expect that the metathesis occurs with the initial substitution of the chloride ligand that occupies the *trans* position with respect to the imido group. This substitution will produce the isomers **II** or **III**. However, the isolated complex **4** is characterized by a singlet in the ³¹P{¹H}-NMR spectrum and by the presence of a doublet for the PMe₃ ligands in the ¹H-NMR spectrum, with a coupling constant $J_{\rm HP}$ of 7.7 Hz. Consequently, the spectroscopic data of **4** are in agreement with structure **I**, in which the two PMe₃ ligands are equivalent and mutually *cis*. We have no evidence for the formation of complexes with either structure **II** or **III**.

In order to rationalize the preferential formation of only isomer I in this reaction, we have performed an EHMO study with the model compound $Mo(NH)(S_2COH)Cl(PH_3)_2$ in the three geometries, I– III. The main electronic features are not affected by the substitution of the terminal 2,4,6-Me₃C₆H₂ group by a single H atom. The absolute energy minimum is calculated to correspond to the experimentally observed isomer I, which is ca. 0.2 eV more stable than II and III.

In view of the limitations of the EHMO method for the prediction of the correct energies, we decided to analyze the fragment molecular orbital (FMO) interactions of the three model compounds. In all cases, the common dithio-ligand, S₂COH, was considered to interact with a metallic fragment of the type d^2 -ML₄ and the geometry defined in IV–VI.

Despite the fact that the presence of the triple bonded imido functionality makes these d^2 -ML₄ fragments unusual, their FMOs can be inferred from the classical C_{2v} -ML₄ fragment [11]. Fig. 1 illustrates the metal FMOs of **IV**. For comparison, the energies of the analogous FMOs of **V** and **VI** have been also included.

They consist of a high-lying σ -hybrid, **3a**', a pair of hybridized d_{xy} and d_{yz} orbitals (**2a**'' and **1a**'') and the **2a**' FMO (d_{xz} orbital). The FMOs **1a**'', **2a**' and **2a**'' show the antibonding combination with the π -contribution of the imido and the chloride ligands. The HOMO **1a**' of **IV** is essentially the $d_{x^2-y^2}$ orbital. The presence of the formally π -donor chloride ligand in the *cis* position with respect to the imido functionality produces a destabilization (four electron repulsion) of the HOMO in the fragments **V** and **VI**. Accordingly, the minimum energy corresponds to the metal fragment **IV**, which is found to be ca. 0.6 eV more stable than the other two structures.

The FMOs of some dithio-ligands have been outlined previously [12], and include two filled in-plane combinations of sulfur lone pairs (in phase, σ_{ip} , and out-ofphase, σ_{op}) and the π -S₂C system. The interaction diagrams for the three isomers (not represented) reveal that the π combinations of the dithio-ligand basically do not participate in the bonding scheme and only the two filled σ -FMOs (σ_{op} and σ_{ip}) contribute to the construction of the MOs.

As stated above, the energy minimum corresponds to isomer I. Moreover, the best overlap populations between the metallic fragments and the S₂COH ligand occurs also for this isomer. In particular, the FMO 1a" shows an appreciable overlap population with the σ_{op} contribution. This interaction has no match for the isomers II or III. Finally, the decrease in the energy difference between I and the other isomers (from 0.6 eV in the metal fragments to 0.2 eV) has its origin in a four electron repulsion between the 1a' fragment (HOMO for IV) and the σ_{ip} FMO.

For a d^2 metal configuration, the presence of the formally π -donor chloride ligand in the *trans* position

Fig. 1. CACAO drawings for the metallic FMOs of IV and comparative energies for the same metallic fragments V and VI.

with respect to the imido ligand is electronically more favorable than the structure containing the chloride ligand occupying a *cis*-coordination site. In conclusion, our calculations indicate that isomer I is the most stable configuration for the model compound $Mo(NH)(S_2COH)Cl(PH_3)_2$ and this fact is in agreement with the preferential formation of this isomer, observed experimentally.

Interaction of solutions of **4** with CO takes place with substitution of one PMe₃ ligand and formation of complex Mo(Nmes)(S₂COMe)Cl(CO)(PMe₃) (**5**) (Eq. (2)). The presence of the CO group was spectroscopically confirmed by IR and was further indicated by the appearance of a doublet at 238.6 ppm in the ¹³C{¹H}-NMR spectrum (² $J_{CP} = 7.6$ Hz).

$$\begin{array}{c} & & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ & & \\ &$$

Other NMR data are collected in Section 2 and need no further comment. As outlined before, the MO analysis of 4 shows a HOMO composed essentially of the filled $d_{x^2-y^2}$ metal orbital. Accordingly, the substitution of one PMe₃ ligand by CO stabilizes the HOMO by the π -acceptor capability of the latter ligand [1b,5,13].

Addition of carbon disulfide to transition metal– phosphine derivatives is a common entry to the chemistry of S₂CPR₃ complexes [14]. The easy dissociation of PMe₃ from complex **1**, makes it a useful candidate for the investigation of this reaction. Treatment of solutions of **1** with one equivalent of carbon disulfide affords compound Mo(Nmes)Cl₂(S₂CPMe₃) (**6**), as an orange microcrystalline solid (Eq. (3)). The S₂CPMe₃ ligand gives characteristic ¹H (doublet at 1.94 ppm, $J_{\rm HP} = 13.8$ Hz) and ³¹P{¹H} (singlet at 42.5 ppm) resonances, attributable to a phosphonium group.

In addition, a ¹³C doublet at 97.5 ppm ($J_{CP} = 78.2$ Hz) can be assigned to the central carbon atom of the S₂CPMe₃ ligand. The chemical shift of this signal is indicative of a trihapto-(S,S',C) coordination [14,15]. The structure displayed in Eq. (3) for complex **6** was proposed on the basis of previous MO studies [16] carried out on related d²-systems that contain a multiple-bonded ligand and the trihapto-(S,S',C) S₂CPR₃ group.

Acknowledgements

Financial support from DGES and Junta de Andalucía are gratefully acknowledged. F.M. thanks the Junta de Andalucía for a research studentship and A.P. thanks the Spanish Ministry of Education for a postdoctoral contract.
