Abstract

Reaction of FcCH₂CH₂P(O)(OH)₂ or FcCH₂P(O)(OH)(OEt) [Fc = Fe(η^5 -C₅H₄)(η^5 -C₅H₅)] with excess CH₂N₂ followed by reduction with Me₃SiCl-LiAlH₄ gives the air-stable primary phosphines FcCH₂CH₂PH₂ and the previously reported analogue FcCH₂PH₂ in high yields. Reduction of 1,1'-Fc'[CH₂P(O)(OEt)₂] [Fc' = Fe(η^5 -C₅H₄)₂] and 1,2-Fc"[CH₂P(O)(OEt)₂] [Fc" = Fe(η^5 -C₅H₅)(η^5 -C₅H₃)] similarly gives the new primary phosphines 1,1'-Fc'(CH₂PH₂)₂ and 1,2-Fc"(CH₂PH₂)₂, respectively. The arsine FcCH₂CH₂AsH₂, which is also air-stable, has been prepared by reduction of the arsonic acid FcCH₂CH₂As(O)(OH)₂ using Zn/HCl. An X-ray structure has been carried out on the arsine, which is only the second structure determination of a free primary arsine. The molybdenum carbonyl complex [1,2-Fc"(CH₂PH₂)₂Mo(CO)₄] was prepared by reaction of the phosphine with [Mo(CO)₄(pip)₂] (pip = piperidine), and characterized by a preliminary X-ray structure determination. However, the same reaction of 1,1'-Fc'(CH₂PH₂)₂ with [Mo(CO)₄(pip)₂] gave [1,1'-Fc'(CH₂PH₂)₂Mo(CO)₄] and the dimer [1,1'-Fc'(CH₂PH₂)₂Mo(CO)₄]₂, characterized by electrospray mass spectrometry. 1,1'-Fc'[CH₂PH₂Mo(CO)₅]₂ and 1,2-Fc"[CH₂PH₂Mo(CO)₅]₂ were likewise prepared from the phosphines and excess [Mo(CO)₅(THF)]. © 2002 Published by Elsevier Science B.V.

Keywords: Air-stable ligands; Ferrocenyl group; Primary phosphine; Primary arsine

1. Introduction

Primary phosphines and arsines, REH_2 (E = P, As), particularly those containing lower alkyl groups, are typically highly air-sensitive, and often pyrophoric, with high toxicity and noxious odors, making them unpleasant and difficult materials to handle. Clearly, there is a desire for compounds of this type with 'user-friendly' characteristics, as recently noted by Katti et al. [1]. Nevertheless, primary phosphines and arsines have a very rich chemistry, promoted by the reactivity of the E–H bond [2,3]. In recent years, there have been a number of reports on the synthesis and use of air-stable primary phosphines. The use of bulky substituents in the mesityl-type phosphines 1 has been perhaps the most general route for stabilizing primary phosphines [4,5], though these are exclusively aryl phosphines. In the area of alkylphosphines Katti and co-workers have recently described a number of remarkably air-stable primary alkylphosphines which contain amide, carboxylate and thiol functional groups; the common feature of the air-stable derivatives is an amide linkage four bonds away from the PH₂ group [1,3,6]. Other air-stable alkyl derivatives include the dibenzobarrellene phosphine **2** [7], together with a range of cationic derivatives of the

general type $[R_3NCH_2CH_2PH_2]^+$ [8]. During our studies into the chemistry of the hydroxymethylphosphine $FcCH_2P(CH_2OH)_2$ (3a) $[Fc = (\eta^5-C_5H_4)Fe(\eta^5-C_5H_5)]$ we discovered that formaldehyde could be eliminated under certain circumstances, giving the primary alkyl

phosphine $FcCH_2PH_2$ (3b), which is completely airstable in the solid and solution states [9]. We subsequently wished to ascertain the generality of this stabilization by the synthesis of related ferrocenederived primary phosphines and arsines, and the results are presented in this paper.

2. Results and discussion

2.1. Synthesis and characterization of primary phosphines

The air-stable primary ferrocene phosphine $FcCH_2PH_2$ (3b) was originally synthesized by reaction of FcCH₂P(CH₂OH)₂ with the formaldehyde-abstracting reagent $Na_2S_2O_5$ [9]. We wished to employ a more general route involving reduction of phosphonate esters, with the expectation that the method could also be employed to prepare a range of related primary phosphines and arsines derived from ferrocene. The reducing agent of choice was a mixture of LiAlH₄ and Me₃SiCl, which has been found to be a highly effective reducing mixture in primary phosphine synthesis [10]. The phosphonic acid monoester FcCH₂P(O)(OEt)OH was a prime candidate for reduction, because it can be synthesized in good yield starting from readily accessible FcCH₂OH and Na[P(O)(OEt)₂] [11]. However, reduction of FcCH2P(O)(OEt)OH with LiAlH4-Me3SiCl gave a very low yield of 3b, presumably due to the formation of insoluble lithium salts which are more difficult to reduce. Subsequently, methylation of FcCH₂P(O)(OEt)OH with excess diazomethane gave the mixed ester FcCH₂P(O)(OMe)(OEt), which was not isolated, but reduced in high yield (>90%) to 3busing LiAlH₄-Me₃SiCl. In a similar fashion, methylation of the known phosphonic acid FcCH₂CH₂P(O)-(OH)₂ [11] with excess CH₂N₂, followed by LiAlH₄-Me₃SiCl reduction gave the primary ethylphosphine FcCH₂CH₂PH₂ (4) in 82% yield. This phosphine was initially isolated as an oil which sublimed under vacuum at 40 °C to give a dark orange crystalline solid, similar to 3b. Similarly formed from the corresponding ethyl phosphonate esters 1,1'-Fc'[CH₂P(O)(OEt)₂]₂ [Fc' = $Fe(\eta^5-C_5H_4)_2$] (which has been prepared previously) $1,2-Fc''[CH_2P(O)(OEt)_2]_2$ [Fc'' = Fe(η^5 -[11] and C_5H_5 (η^5 - C_5H_3)] were the bis-primary phosphines 5 and 6, respectively, isolated as yellow oils; phosphine 6 sublimes under vacuum as a dark orange oil. The 1,2phosphonate isomer has not been prepared previously, and was prepared by reaction of 1,2-Fc"(CH₂Cl)₂ with excess P(OEt)₃. The phosphines **4**–**6** are soluble in petroleum spirits and possess a mild odor typical of primary phosphines.

The phosphines give the expected ³¹P-NMR signals [δ ³¹P: -135.8 (4), -132.0 (5), and -127.6 (6)] appearing as triplets in their ¹H-coupled spectra, with ¹J(PH) in the range 195-198 Hz. Other primary phosphines give very similar values, e.g. H₂PCH₂CH₂PH₂ (193 Hz) [12] and 3b (194 Hz) [9]. The electrospray (ES) mass spectra of phosphines 4-6 are dominated by the $[M]^+$ ion, as also observed for a number of other ferrocene compounds by this technique, though peaks due to [M +H]⁺ may also be observed. Spectra were typically recorded with added AgNO₃ which generates silver complexes in situ, giving $[M+Ag]^+$ ions, as has been observed for other ferrocenyl phosphines [13]. The IR spectra showed bands characteristic of vP-H stretches, at 2294, 2290 and 2265 cm^{-1} for 4, 5, and 6, respectively.

Phosphine 4 appears to be completely air-stable (a solid sample exposed to air for 2 years showed no decomposition) while 6 is stable in air for at least several months, and 5 appears to be stable for several weeks. Longer exposure of 5 leads to some degradation, monitored by ³¹P-NMR spectroscopy; residual phosphine is amenable to repurification by silica flash column chromatography using petroleum spirits as the eluting solvent. To provide a comparison, samples of the known primary ferrocene-phosphines FcPH₂ [14] and 1,1'-Fc'(PH₂)₂ [15] were synthesized by LiAlH₄-Me₃-SiCl reduction of FcP(O)(OEt)₂ and 1,1'-Fc'[P(O)-(OEt)₂]₂, respectively, and their air-sensitivity ascertained by allowing samples to stand in air for several days. As far as we are aware, the air-sensitivity of these phosphines has not been explicitly discussed in the literature, though they have been used as starting reagents for the synthesis of other phosphines, typically using inert atmosphere techniques. 1,1'-Fc'(PH₂)₂ was the most rapidly oxidized in air, with a sample left for 3 days showing complete consumption of the original phosphine, and formation of a mixture of primary phosphine oxide $[RP(O)H_2]$ and phosphinic acid [RP(O)(OH)H] groups. Air exposure of solutions of 1,1'-Fc'(PH₂)₂ in organic solvents led to immediate formation of a yellow precipitate, demonstrating the highly air-sensitive nature of this phosphine, in marked contrast to **5**. FcPH₂ was less reactive towards air, but was also oxidized by air over a period of several days. After 5 days exposure to air, the ³¹P-NMR spectrum showed a mixture of the primary phosphine oxide and phosphinic acid with very little residual phosphine present. These observations suggest that the presence of the alkyl spacer is a key factor in providing air stability in the ferrocenyl-phosphine system. Further studies are necessary to determine the effect of even longer alkyl spacers on phosphine stability.

2.2. Synthesis and characterization of the primary arsine *FcCH*₂*CH*₂*AsH*₂

Having synthesized a number of air-stable primary phosphines, we wished to synthesize a corresponding primary arsine, to see if the ferrocene-based stabilization was extended to arsines. One of the classical methods for the synthesis of primary arsines involves the reduction of an arsonic acid [16]. FcCH₂CH₂As(O)(OH)₂ is readily available [from FcCH2CH2Br and sodium arsenite] [11]. Reduction of this with Zn/HCl in a two-phase water-petroleum spirits system gave the primary arsine 7 as a crystalline orange solid. The arsine, like the corresponding phosphine 4, appears to be air-stable, though a detailed study was not carried out. The compound is soluble in petroleum spirits and other organic solvents (except lower alcohols and DMSO), has the expected unpleasant but mild odor, and sublimes under vacuum to give single crystals suitable for an Xray diffraction study. To the best of our knowledge, there has only been one previous structure determination of a free primary arsine, that of 1 ($\mathbf{R} = {}^{i}\mathbf{Pr}$) [4], though the silvl-arsine $2,4,6^{-i}$ Pr₃C₆H₂Si(^{*t*}Bu)(AsH₂)₂ has also been characterized [17]. Only a few transition metal complexes of primary arsines have also been structurally characterized, e.g. [PhAsH₂-Cr(CO)₅] [18]. We are unaware of any reports of ferrocene-derived primary arsines in the literature. This contrasts with the much larger number of tertiary ferrocenyl arsines such as those containing AsMe₂ groups [19].

The molecular structure of 7 is shown in Fig. 1, together with the atom numbering scheme. Selected bond lengths and angles are given in Table 1. The structure confirms the compound as a primary arsine. The CH₂CH₂ group is slightly disordered, and extends away from the ferrocenyl moiety, with major [95%; C(1) and C(2)] and minor [5%; C(111) and C(112)] components of the disorder modeled. The CH₂CH₂AsH₂ substituent is approximately coplanar with the Cp ring to which it is attached, with torsion angles C(11)–C(1)–C(2)–As 177.19° and C(11)–C(111)–C(112)–As 175.91°. The As–C bond distance, 1.966(6) Å, is highly

Fig. 1. Molecular structure of $FcCH_2CH_2AsH_2$ (7), showing the atom numbering scheme. Thermal ellipsoids are at the 50% probability level.

comparable to that of the $R = {}^{i}Pr$ derivative of 1, 1.968(3) Å [4]. Single crystals of the corresponding phosphine 4 were also obtained by sublimation of the compound under vacuum, and a preliminary X-ray structure determination showed the compound to be isomorphous and hence isostructural to 7. A full structure determination was, therefore, not continued.

2.3. Molybdenum carbonyl complexes of ferrocenederived primary phosphines

Molybdenum carbonyl complexes of the phosphines **5** and **6** were prepared in the expectation that crystalline complexes would be formed, providing additional characterization of the phosphines themselves, which were isolated as oils. A wide range of molybdenum carbonyl complexes of phosphines are known, for example, primary phosphines readily react with $L_2M(CO)_4$ [M = Cr, Mo, W; L_2 = norbornadiene or L = piperidine (pip)] to give complexes (RPH₂)₂M(CO)₄ [20] and reactions between RPH₂ (R = 1-adamantyl) and M(CO)₆ (M = Cr, Mo, W) giving [Mo(CO)₅-(RPH₂)] have also been described [21]. Ferrocenyl phosphine derivatives of Mo(CO)₅ [9] and M(CO)₄ (M = Cr, Mo, W) have been previously reported [9,22].

The reaction of $1,2-Fc''(CH_2PH_2)_2$ (6) with $[Mo(CO)_4(pip)_2]$ in refluxing dichloromethane gave the expected complex 8 as the sole product, a yellow crystalline solid which gave satisfactory microanalytical data. Coordination of the phosphine resulted in a shift of the ³¹P-NMR signal from ca. δ –128 in the free phosphine to ca. δ -79 in the complex. Crystals of 8 were obtained from dichloromethane-petroleum spirits, and to fully characterize the complex, an X-ray structure determination was carried out. However, the crystal was weakly diffracting, and coupled with ambiguities in space group assignment and likely disorder, an adequate refinement was not obtained, so discussion of bond parameters was clearly not justified. However, the overall structure of the complex (Fig. 2) is clear, and confirms the formulation as a chelate complex formed by the bidentate bis(primary) phosphine, with the seven-

membered ring adopting a boat conformation. The negative-ion electrospray mass spectrum of **8** in methanol with added NaOMe gave a very strong $[M-H]^-$ ion as the base peak, due to deprotonation of one of the PH hydrogens. We have used this ionization technique previously in ES characterization of molybdenum carbonyl complexes of FcCH₂PH₂ [9]; the alternative addition of OMe⁻ to a coordinated CO ligand [23] was not observed for this complex.

The reaction of $1,1'-Fc'(CH_2PH_2)_2$ (5) with $[Mo(CO)_4(pip)_2]$ in refluxing dichloromethane yielded two compounds. The major product was the expected chelate complex **9a**, isolated as a yellow crystalline solid using silica thin layer chromatography, and fully characterized. The negative ion ES mass spectrum at a cone voltage of 10 V showed both $[M-H]^-$ (m/z 487) and $[M-H-CO]^-$ ions; increasing the cone voltage to 60 V results in the sequential loss of up to all four CO ligands. The minor product **9b**, also isolated by chromatography, was identified by ESMS as the dimeric species $[1,1'-Fc'(CH_2PH_2)_2Mo(CO)_4]_2$. Thus, the ES spectrum of **9b** in methanol with added NaOMe gave a single ion due to [**9b** $-H]^-$ at m/z 971, with no

evidence of the monomeric species. The formation of **9b** could be minimized (but not eliminated) by carrying out the reaction in dilute solution. The ES spectrum of the reaction mixture showed both **9a** and **9b**, but no evidence for larger oligomers.

The Mo(CO)₅ derivatives of phosphines 5 and 6 have also been synthesized from [Mo(CO)₆], via the labile intermediate complex $[Mo(CO)_5(THF)]$ (THF = tetrahydrofuran) [24]. Thus, reaction of 5 with a large excess $[Mo(CO)_{5}(THF)]$ the of gave complex 1.1'- $Fc'[CH_2PH_2Mo(CO)_5]_2$ (10) as the sole product. Again, the reaction can be conveniently monitored by ³¹P-NMR spectroscopy, with a shift from δ -132 for the free ligand to δ -62.5 on complex formation. The complex was purified by silica thin layer chromatography, and was isolated as a yellow crystalline solid. The negative-ion ES spectrum of 10 in methanol with added NaOMe gave solely the $[M-H]^-$ ion at a cone voltage of 5 V and, as the cone voltage is increased, there is stepwise loss of all 10 CO ligands, as shown in Fig. 3. The reaction of 1,2-Fc"(CH2PH2)2 with [Mo(CO)5-(THF)] gave the analogous complex 1,2-Fc"[CH₂PH₂- $Mo(CO)_{5}_{2}$ (11) as the principal product. The electrospray mass spectrum in methanol with added NaOMe showed $[M-H]^-$ and $[M+OMe]^-$ ions. Complexes 10 and 11 both give triplets in their proton-coupled ³¹P-NMR spectra, with ${}^{1}J(PH)$ ca. 320 Hz, consistent with the presence of coordinated PH₂ groups.

Fig. 3. Negative ion ES spectra (in methanol with added sodium methoxide) of 1,1'-Fc'[CH₂PH₂Mo(CO)₅]₂ (10) at various cone voltages, showing the loss of all ten CO ligands with increasing cone voltage.

The molybdenum carbonyl derivatives of phosphines **5** and **6** are easily prepared and handled, and provide additional evidence for the identity of the phosphines themselves, in the form of satisfactory microanalytical and spectroscopic data. The complexes are yellow crystalline solids, which turn green upon prolonged exposure (several months) to air. The Mo(CO)₄ derivatives decompose on heating, whereas the Mo(CO)₅ derivatives have clearly defined melting points. Apart from complex **8**, the yields of the Mo complexes were relatively poor, presumably due to decomposition and losses on purification.

3. Conclusions

We have shown that the incorporation of $-CH_2-$ or $-CH_2CH_2-$ spacer groups in ferrocene-derived primary phosphines and an arsine dramatically increases their air stability compared with phosphines such as 1,1'-Fc'(PH_2)_2, where the PH_2 groups are bonded directly to the Cp rings. The resulting compounds, which are easily handled, and in some cases crystalline and sublimable, can be considered to be 'user-friendly'

primary phosphine ligands, complementary to FcCH₂PH₂ prepared earlier by us, and to the range of other stable primary phosphines reported by other workers. The anticipated reactivity of the P-H (and As-H) bonds in these materials, coupled with the longstanding interest in the versatile and flexible coordination chemistry of ligands such as dppf $[1,1'-Fc'(PPh_2)_2]$ [25] and recently synthesized analogues such as 1,1'-Fc'(CH₂PPh₂)₂ [26] suggests that the phosphines reported herein could be valuable precursors for the synthesis of new ferrocene-based phosphine ligands. While the factors providing air stability in the ferrocenyl primary phosphine/arsine system are not currently understood, the synthesis of related compounds may provide insights, and studies in this area are planned.

4. Experimental

4.1. General experimental procedures

General experimental techniques and instrumentation were as described in a recent publication [11]. Elemental microanalyses were carried out by the Campbell Microanalytical Laboratory, University of Otago, New Zealand. All reactions were carried out under a nitrogen atmosphere unless otherwise stated, using solvents which were dried and distilled prior to use. Petroleum spirits refers to the fraction of boiling point range 40– 60 °C. IR spectra of primary phosphines and their Mo complexes were recorded as CH_2Cl_2 solutions. NMR spectra were recorded in $CDCl_3$ solution unless otherwise stated. Numbering of monosubstituted and 1,1'-disubstituted ferrocenyl compounds was as used previously [11]. For the 1,2-disubstituted compounds the numbering scheme used is shown in Scheme 1.

GC–MS data were acquired using a Hewlett–Packard 5890 series 1 gas chromatograph coupled to a Hewlett–Packard 5970 series mass selective detector operating at 70 eV. Samples were introduced as CH_2Cl_2 solutions and were eluted using a 50–280 °C temperature ramp, at 10 °C min⁻¹ with a 3 min solvent delay and an HP1 column containing crosslinked methylsilicone gum.

Electrospray mass spectra were recorded as described before [11], using MeOH as the solvent and mobile phase. A small quantity of aq. AgNO₃ (0.1 M, ca. 1 mmol ml⁻¹ of sample solution) was added to the primary phosphines to generate charged silver complexes in situ [13]. Small quantities of NaOMe in MeOH were added to the Mo carbonyl complexes to promote ionization by deprotonation [23]. Ion assignment was assisted by comparison of observed and calculated isotope distribution patterns, the latter obtained using the ISOTOPE program [27].

The following compounds were used as supplied from commercial sources: Mo(CO)₆ (Pressure Chemical Co.), triethylphosphite (BDH), LiAlH₄ (Aldrich), zinc powder (Prolabo) and Me₃SiCl (Aldrich). Other chemicals used were at least of reagent grade. The compounds $FcCH_2CH_2P(O)(OH)_2$ [11], $FcCH_2CH_2As(O)(OH)_2$ [11], FcCH₂P(O)(OEt)(OH) [11], FcP(O)(OEt)₂ [11], 1,1'-Fc'[P(O)(OEt)₂]₂ [11], 1,1'-Fc'[CH₂P(O)(OEt)₂]₂ [11], $[Mo(CO)_4(pip)_2]$ [28] and 1,2-Fc["](CH₂OH)₂ [29] were prepared by the literature procedures, and diazomethane was prepared from nitrosomethylurea and following the literature procedure [30]. KOH [Mo(CO)₅(THF)] was generated in situ by modification of the literature method [24]. This involved irradiating a solution of Mo(CO)₆ in THF using a Lighting Technology MBF 400 W lamp, placed 10 cm from the reaction vessel (Pyrex Schlenk flask).

4.2. Synthesis of $FcPH_2$

To a slurry of LiAlH₄ (0.32 g, 8.5 mmol) and Me₃SiCl (1 ml, 8.5 mmol) in THF (10 ml) was added a solution of FcP(O)(OEt)₂ (0.91 g, 2.8 mmol) in THF (10 ml). The

Scheme 1. Atom numbering scheme used for 1,2-disubstituted ferrocene compounds.

reaction mixture was stirred for 12 h, and then MeOH (5 ml) added carefully with stirring to destroy excess LiAlH₄, and the solvent removed under reduced pressure. The residue was extracted with petroleum spirits (5 × 10 ml) and the combined organic fractions filtered through celite. The solvent was then removed to give 0.5 g (87%) of FcPH₂ as a brown oil that crystallized on standing. ³¹P-NMR, δ –143.3 [t, ¹*J*(PH) 203], lit. δ ³¹P –145.1 [14].

4.3. Synthesis of 1, 1'-Fc' $(PH_2)_2$

A solution of 1,1'-Fc'[P(O)(OEt)₂]₂ (0.54 g, 1.2 mmol) in THF (5 ml) was added to a suspension of LiAlH₄ (0.27 g, 7 mmol) and Me₃SiCl (0.9 ml, 7 mmol) in Et₂O. The reaction mixture was stirred at room temperature (r.t.) for 12 h and MeOH (5 ml) was added carefully with stirring to destroy excess LiAlH₄. The solvent was removed under reduced pressure and the residue extracted with petroleum spirits (5 × 10 ml). The combined organic fractions were filtered through celite and the solvent removed to give 0.24 g (82%) of 1,1'-Fc'(PH₂)₂ as a brown oil that crystallized on standing. ³¹P-NMR, δ –143.8. Lit. δ ³¹P (C₆D₆) –145.5 [15a].

4.4. Synthesis of $FcCH_2PH_2$ (3b)

Excess ethereal CH₂N₂ was added to a slurry of FcCH₂P(O)(OEt)(OH) (0.99 g, 3.2 mmol) in MeOH (5 ml) and the mixture stirred until the solid had completely dissolved. Excess CH₂N₂ was removed by purging with nitrogen, and the solvent was removed under vacuum. The residual brown oil was dissolved in THF (5 ml) and added dropwise to a slurry of LiAlH₄ (0.7 g, 19.2 mmol) and Me₃SiCl (2.4 ml, 19.2 mmol) in THF (10 ml). The mixture was stirred for 12 h and MeOH (5 ml) was carefully added dropwise to destroy excess LiAlH₄. The solvent was removed under vacuum and the residue extracted with petroleum spirits (5×10 ml), the combined extracts filtered through celite, and the solvent removed under vacuum to give FcCH₂PH₂ as a crystalline yellow-orange solid, yield 0.69 g, 92%. The sample was spectroscopically identical to a sample prepared by the literature procedure [9]. ³¹P-NMR (CDCl₃), δ -129.09 [t, ¹J(PH) 193 Hz].

4.5. Synthesis of $FcCH_2CH_2PH_2$ (4)

Excess ethereal CH_2N_2 was added slowly to a slurry of FcCH₂CH₂P(O)(OH)₂ (0.39 g, 1.34 mmol) in CH₂Cl₂ (5 ml) and stirred until the solid had completely dissolved. Nitrogen was bubbled through the solution to remove excess CH_2N_2 , and then the solvent was removed under vacuum. The residue was dissolved in THF (5 ml) and added dropwise to a slurry of LiAlH₄ (0.25 g, 6.7 mmol) and Me₃SiCl (0.72 g, 6.7 mmol) in THF (10 ml). The resulting mixture was stirred for 12 h at r.t., MeOH (5 ml) carefully added dropwise to destroy excess LiAlH₄, and the mixture stirred for 30 min. The solvent was removed under vacuum and the residue dissolved in petroleum spirits (20 ml). The yellow solution was filtered through celite and the solvent removed to give 0.27 g (82%) of FcCH₂CH₂PH₂ as a yellow powder. Melting point (m.p.) 53-55 °C. Found: C, 58.7; H, 6.0. C₁₂H₁₅FeP requires C, 58.6; H, 6.1%. ³¹P-NMR, δ –135.8 [t, ¹J(PH) 195]. ¹³C{¹H}-NMR, δ 15.50 [d, ${}^{1}J(PC)$ 8.4, PCH₂], 33.25 [d, ${}^{2}J(PC)$ 3, PCH₂CH₂], 67.33 (s, C3), 68.05 (s, C2), 68.57 (s, C4), 89.04 [d, ${}^{3}J(PC)$ 6, C1]. ¹H-NMR, δ 2.57 [2H, dt, ²*J*(PH) 2.5, ³*J*(HH) 7, PCH₂], 2.74 [2H, dt, ¹*J*(PH) 194, ³J(HH) 7, PH₂], 4.08–4.12 (11H, m, CH₂CH₂PH₂/H2/ H3/H4). ESMS (cone voltage 40 V, with added AgNO₃), $[M]^+$ (*m*/*z* 246, 8%), $[M+Ag]^+$ (*m*/*z* 353/355, 100%). GC-MS: $[M]^+$ (*m*/*z* 246), $[M-PH_2]^+$ (*m*/*z* 213), $[FcCH_2]^+$ (*m*/*z* 199), $[FeCp]^+$ (*m*/*z* 121), $[Fe]^+$ (*m*/*z* 56). IR $(v_{\text{max}}, \text{ cm}^{-1})$: 2294 (m, vPH).

4.6. Synthesis of 1, 1'-Fc' $(CH_2PH_2)_2$ (5)

1,1'-Fc'[CH₂P(O)(OEt)₂]₂ (0.45 g) was dissolved in THF (5 ml) and added to a slurry of LiAlH₄ (0.18 g, 4.7 mmol) and Me₃SiCl (0.53 g, 4.7 mmol) in THF (10 ml) and the mixture stirred at r.t. for 6 h. Methanol (5 ml) was carefully added dropwise to destroy excess LiAlH₄, the mixture stirred for 30 min and the volatiles removed under vacuum. The residue was dissolved in petroleum spirits (20 ml), filtered through celite and the solvent removed from the filtrate to give 5 as a yellow oil (0.16) g, 62%). ³¹P-NMR, δ –132.0 [t, ¹*J*(PH) 196]. ¹³C{¹H}-NMR, δ 14.30 [d, ¹J(PC) 8.7, CH₂P], 68.29 (s, C3), 68.57 [d, ³*J*(PC) 2.7, C2], 89.30 [d, ²*J*(PC) 3, C1]. ¹H-NMR, δ 1.54 (4H, br s, CH₂P), 2.93 [4H, dt, ¹J(PH) 192, ³*J*(HH) 7, PH₂], 4.04 (8H, s, H2/H3). ESMS (cone voltage 40 V, with added AgNO₃) $[M]^+$ (*m/z* 278, 100%), $[M+Ag]^+$ (*m*/*z* 385/387, 45%). IR (cm⁻¹): 3082(m), 2922(m), 2290(s, vPH₂), 1083(m), 1039(m), 1019(w), 927(m), 859(w), 852(w), 823(w), 485(m).

4.7. Synthesis of 1,2-Fc" (CH₂PH₂)₂ (6)

1,2-Fc"(CH₂Cl)₂ was generated by a minor modification of the literature procedure [31] as follows: To 1,2-Fc"(CH₂OH)₂ (0.23 g, 0.93 mmol) in THF (10 ml) under nitrogen was added pyridine (0.15 g, 1.86 mmol) and freshly distilled PCl₃ (0.25 g, 1.86 mmol). The reaction mixture was stirred for 1 h, filtered, and the filtrate evaporated to dryness to give crude 1,2-Fc"(CH₂Cl)₂. Triethylphosphite (3 ml) was added and the mixture refluxed for 4 h. Volatiles were removed under vacuum and the resulting brown oil purified by alumina flash column chromatography using an EtOAc to MeOH solvent gradient. The 1,2-Fc"[CH₂P(O)(OEt)₂] was isolated as a viscous brown oil (0.39 g, 85%). This was dissolved in THF (5 ml) and added to a slurry of LiAlH₄ (0.30 g, 8 mmol) and Me₃SiCl (0.87 g, 8 mmol) in THF (10 ml) under nitrogen, and the mixture stirred for 9 h. Methanol (5 ml) was carefully added dropwise to destroy excess LiAlH₄, the mixture stirred for 30 min, and the volatiles removed under vacuum. The residue was dissolved in petroleum spirits (20 ml), filtered through celite, and the solvent removed giving the product $\mathbf{6}$ as a yellow crystalline solid which melted on warming to r.t. Yield 0.18 g, 80%. ³¹P-NMR, δ -127.6 [t, ¹J(PH) 198]. ¹³C{¹H}-NMR, δ 12.86 [d, ¹J(PC) 10, CH₂P], 65.64 (s, C1), 67.39 (s, C2), 69.43 (s, C4), 86.94 (s, C3). ¹H-NMR, δ 2.62 (4H, m, CH₂P), 2.94 [4H, dt, $^{1}J(PH)$ 196, $^{3}J(HH)$ 7, PH₂], 4.00 [1H, t, $^{3}J(HH)$ 2.5, H1], 4.05 (5H, s, H4), 4.01 [2H, d, ³J(HH) 2.5, H2]. ESMS (cone voltage 20 V, with added AgNO₃) [M+ Ag]⁺ $(m/z \ 385/387, \ 100\%)$. IR (cm^{-1}) : 3097(w), 2916(m), 2285(s, vPH₂), 1105(s), 1080(m), 1034(m), 997(m), 929(w), 819(m), 485(m).

4.8. Synthesis of $FcCH_2CH_2AsH_2$ (7)

FcCH₂CH₂As(O)(OH)₂ (0.11 g, 0.33 mmol) was dissolved in 0.13 M aq. NaOH (10 ml), and to this was added powdered zinc (0.21 g, 3.3 mmol) and petroleum spirits (15 ml). The mixture was placed under a nitrogen atmosphere and concentrated HCl (10 ml) added dropwise with stirring over 10 min. The layers were separated and the aqueous phase extracted with petroleum spirits (10 ml). The combined organic extracts were dried over MgSO₄, filtered, and the solvent removed to give 0.055 g (57%) of 7 as a yellow oil that crystallized on standing. M.p. 44-46 °C. Found: C, 50.3; H, 5.6. C₁₂H₁₅AsFe requires 49.7; H, 5.2%. ¹³C{¹H}-NMR, δ 14.02 (s, AsCH₂), 33.55 (s, AsCH2CH2), 67.57 (s, C2), 68.26 (s, C3), 68.84 (s, C4), 90.16 (s, C1). ¹H-NMR, δ 1.84 (2H, m, CH₂As), 2.24 [2H, t, ${}^{3}J(HH)$ 6, AsH₂], 2.65 [2H, t, CH₂CH₂As, ${}^{3}J(HH)$ 7.9], 4.09 [4H, m, ${}^{3}J(HH)$ 1.5, H2/H3], 4.14 (5H, s, H4). GC-MS [M]⁺ (*m*/*z* 290), [FcCH₂CH₂]⁺ $(m/z \ 213), [M-AsH_3]^+ (m/z \ 212), [CpFe]^+ (m/z \ 121),$ $[Fe]^+$ (*m*/*z* 56).

4.9. Synthesis of $[1,2-Fc''(CH_2PH_2)_2Mo(CO)_4]$ (8)

Bisphosphine **6** (0.06 g, 0.23 mmol) was dissolved in CH₂Cl₂ (5 ml) under nitrogen, and a solution of $[Mo(CO)_4(pip)_2]$ (0.08 g, 0.23 mmol) in CH₂Cl₂ (5 ml) added. The solution was refluxed and monitored by ³¹P-NMR until reaction was deemed complete (ca. 2 h). The solution was concentrated and purified by silica flash column chromatography using 1:1 CH₂Cl₂–petroleum spirits as the eluting solvent. The solvent was removed giving **8** as a bright yellow powder, 0.092 g (82%). M.p. 133–135 °C. Found: C, 39.7; H, 3.5. C₁₆H₁₆FeMoO₄P₂

127

requires C, 39.5; H, 3.3%. ${}^{31}P{}^{1}H{}$ -NMR, δ -78.5 [${}^{1}J(PH)$ 312 in ${}^{1}H$ -coupled spectrum]. ESMS (cone voltage 5 V with added NaOMe), [M-H]⁻ (*m/z* 485, 100%). IR (cm⁻¹) 2960(w), 2917(w), 2028(vs), 1926(vs), 1105(w), 1075(w), 1010(w), 931(m), 6060(w), 583(w).

4.10. Synthesis of $[1,1'-Fc'(CH_2PH_2)_2Mo(CO)_4]$ (9a) and $[1,1'-Fc'(CH_2PH_2)_2Mo(CO)_4]_2$ (9b)

A solution of 1,1'-Fc'(CH₂PH₂)₂ (**5**) (0.056 g, 0.2 mmol) in CH₂Cl₂ (5 ml) was added to a solution of [Mo(CO)₄(pip)₂] (0.076 g, 0.2 mmol) and the solution refluxed for 2 h. The solvent was removed under vacuum and the products **9a** (0.015 g, 15%) and **9b** (0.002 g) were isolated from the residue using silica thin layer chromatography with 4:6 CH₂Cl₂-petroleum spirits as the developing solvent.

4.10.1. Complex 9a

M.p. 146–148 °C (dec.). Found: C, 39.8; H, 3.1. $C_{16}H_{16}FeMoO_4P_2$ requires C, 39.5; H, 3.3%. ³¹P-NMR, δ –79.8 [tm, ¹*J*(PH) 308]. ¹H-NMR, δ 2.89 [4H, m, CH₂P], 4.18 [4H, t, ³*J*(HH) 1.7, H3], 4.23 [4H, t, ³*J*(HH) 1.7, H2], 4.76 [dm, ¹*J*(PH) 311, PH₂]. ESMS (cone voltage 5 V with added NaOMe), [M–H]⁻ (*m*/*z* 487, 100%), [M–H–CO]⁻ (*m*/*z* 459, 98%). IR (cm⁻¹): 2984(w) 2027(s), 1909(s), 1041(w), 937(w), 609(w), 579(w).

4.10.2. Complex 9b

ESMS (cone voltage 5 V with added NaOMe) $[M - H]^{-}$ (*m*/*z* 971, 100%).

4.11. Synthesis of 1, 1'-Fc' [CH₂PH₂Mo(CO)₅]₂ (10)

Mo(CO)₆ (1.62 g, 6 mmol) was dissolved in THF (15 ml) under nitrogen and a solution of 1,1'-Fc'(CH₂PH₂)₂ (5) (0.057 g, 0.2 mmol) in THF (5 ml) added. The solution was exposed to UV light for 3 h, the solvent removed under vacuum and excess Mo(CO)₆ removed by sublimation under vacuum at 45 °C over 2 days. The residue was dissolved in CH₂Cl₂ (2 ml) and purified by silica thin layer chromatography using 4:6 CH₂Cl₂petroleum spirits as the eluting solvent. The solvent was removed to give 0.052 g (36%) of 10 as a yellow crystalline solid. M.p. 138-142 °C. Found: C, 35.3; H, 2.1. C₂₂H₁₆FeMo₂O₁₀P₂ requires C, 35.2; H, 2.2%. ³¹P-NMR, $\delta = -62.5$ [t, ¹J(PH) 320]. ¹H-NMR, $\delta = 2.89$ (4H, m, CH₂P), 4.14 (8H, br s, H2/H3), 4.36 [4H, dt, ¹J(PH) 319, ${}^{3}J(HH)$ 7, PH₂]. ESMS (cone voltage 5 V with added NaOMe,) $[M-H]^{-}$ (*m*/*z* 749, 100%). IR (cm⁻¹): 3053(w), 2990(w), 2076(s), 1941(s), 928(w), 876(w), 606(m), 582(m).

4.12. Synthesis of 1,2-Fc" [CH₂PH₂Mo(CO)₅]₂ (11)

This complex was prepared by a similar method to 10, starting from Mo(CO)₆ (0.361 g, 1.3 mmol) and 1,2- $Fc''(CH_2PH_2)_2$ (6) (0.038 g, 0.13 mmol), except that the CH₂Cl₂ extract was treated with activated charcoal, and chromatographic separation used 4:6 Et₂O-petroleum spirits, giving 0.025 g (24%) of 11 as a yellow powder. M.p. 119-121 °C. Found: C, 35.5; H, 2.3. C₂₂H₁₆Fe- $Mo_2O_{10}P_2$ requires C, 35.2; H, 2.2%. ³¹P-NMR, δ – 61.4 [t, ${}^{1}J(PH)$ 318]. ${}^{13}C{}^{1}H$ -NMR, δ 21.90 [d, ${}^{1}J(PC)$ 22, CH₂], 67.51 (s, C3), 68.33 (s, C2), 70.04 (s, C4), 83.64 $[d, {}^{2}J(PC) 5, C1], 204.6 [d, {}^{2}J(PC) 9, CO], 208.4 [d,$ $^{2}J(PC)$ 24, CO]. ¹H-NMR, δ 2.93 (4H, m, CH₂PH₂), 4.13 (5H, s, H4), 4.20 [1H, dd, ³J(HH) 2.5, H3], 4.24 [2H, d, ³*J*(HH) 2.5, H2], 4.40 [4H, dt, ¹*J*(PH) 319, ${}^{3}J(\text{HH})$ 6.7, PH₂]. ESMS (cone voltage 10 V with added NaOMe), $[M-H]^{-}$ (*m*/*z* 749, 100%), $[M+OMe]^{-}$ (*m*/*z* 781, 28%). IR (cm⁻¹): 2955(w), 2925(w), 2871(w), 2349(w), 2076(s), 1948(s), 1937(s), 1919(s), 1916(s), 1106(w), 1090(w), 1038(w), 999(w), 927(w), 882(w), 606(m), 582(m).

4.13. Crystal structure determinations of FcCH₂CH₂PH₂ (4) and FcCH₂CH₂AsH₂ (7)

Crystals were obtained by sublimation onto a watercooled (ca. 15 $^{\circ}$ C) cold finger at 30 $^{\circ}$ C under vacuum (ca. 1 mmHg).

Crystal data for 4: C₁₂H₁₅FeP, M = 245.1, monoclinic, space group = $P2_1/c$, a = 10.382(3), b = 7.550(2), c = 14.247(4) Å, $\beta = 96.870(4)^\circ$, V = 1108.82(8) Å³.

Crystal data for 7: $C_{12}H_{15}AsFe$, M = 290.01, monoclinic, space group = $P2_1/c$, a = 14.3996(1), b = 7.5871(1), c = 10.4835(1) Å, $\beta = 97.496(1)^{\circ}$, V = 1135.55(2) Å³, T = 293(2) K, Z = 4, F(000) = 584, $\rho_{calc} = 1.696$ g cm⁻³, μ (Mo-K_{α}) = 4.18 mm⁻¹, 10760 reflections measured, 4587 unique (R_{int} 0.0257) which were used in all calculations.

The data were collected on a Bruker AXS SMART diffractometer at 293(2) K with $1.4 < \theta < 26.6^{\circ}$, and the Fe and As atoms located by Patterson methods. The remainder of the structure developed routinely using direct methods with full-matrix least-squares refinement based on F^2 . Atoms C(1) and C(2) were each disordered over two positions with occupancies of 0.95 and 0.05. Hydrogen atoms were placed in calculated positions except for the As–H hydrogens, which were not located. Refinement converged to $R_{\rm F} = 0.043$, $wR(F^2) = 0.1051$ (all data), where $w = [\sigma^2(F_{\rm o})^2 + (0.0514P^2 + 2.88P]^{-1}$ and $P = (F_{\rm o}^2 + 2F_{\rm c}^2)/3$. The largest residual electron density peaks in the final density map did not exceed 0.614 and -1.108 e Å⁻³.

4.14. Crystal structure determination of $[1,2-Fc''(CH_2PH_2)_2Mo(CO)_4]$ (8)

Suitable crystals of the complex were grown from a CH_2Cl_2 -petroleum spirits solution at -20 °C. The crystal proved to be weakly diffracting and the data set was of poor quality. Attempts at solving the structure in space group $I4_1/a$ were partially successful, but adequate refinement could not be achieved.

Crystal data: $C_{16}H_{16}FeO_4P_2Mo$, M = 486, tetragonal, space group = $I4_1/a$, a = b = 35.0413(1), c = 6.2610(1)Å, V = 7687.84(1) Å³.

5. Supplementary material

Crystallographic data for the structural analysis have been deposited with the Cambridge Crystallographic Data Centre, CCDC No. 187575. Copies of this information may be obtained free of charge from The Director, CCDC, 12, Union Road, Cambridge CB2 1EZ, UK (Fax: +44-1223-336033) or e-mail: deposit@ ccdc.cam.ac.uk or http://www.ccdc.cam.ac.uk.

Acknowledgements

We thank the University of Waikato for financial support (including a scholarship to S. R. A.), Jannine Sims for collection of GC–MS data, Associate Professor Cliff Rickard (University of Auckland) for the X-ray data collection, Professor Alistair Wilkins (University of Waikato) for helpful discussions on GC–MS, and Professor Brian Nicholson (University of Waikato) for assistance with the X-ray crystallography.
