#### Abstract

The reactions of $\mathrm{SmI}_{2}(\mathrm{THF})_{x}$ with $\left[\mathrm{Cp}^{\prime} \mathrm{Mo}(\mathrm{CO})_{3}\right]_{2} \mathrm{Hg}\left(\mathrm{Cp}^{\prime}=\mathrm{C}_{5} \mathrm{H}_{5}^{-}\right.$or $\left.\mathrm{C}_{5} \mathrm{Me}_{5}^{-}\right)$in THF at ambient temperature have been investigated. In the case of $\left[\left(\mathrm{C}_{5} \mathrm{H}_{5}\right) \mathrm{Mo}(\mathrm{CO})_{3}\right]_{2} \mathrm{Hg}$, a new complex of $\left[(\mathrm{THF})_{4} \mathrm{I}_{2} \mathrm{Sm}(\mu-\mathrm{OC}) \mathrm{Mo}\left(\mathrm{CO}_{2}\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)\right] 1\right.$ was afforded. However. in the reaction involving $\left[\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right) \mathrm{Mo}(\mathrm{CO})_{3}\right]_{2} \mathrm{Hg}$ the analog cannot the obtained, but instead the dimeric $\left[\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right) \mathrm{Mo}(\mathrm{CO})_{3}\right]_{2} 2$. Both complexes 1 and 2 have been characterized by X-ray crystallography. In 1 the cooperative activation of CO between $\mathrm{Sm}^{3+}$ and Mo was observed. The structure of complex $\mathbf{1}$ is the first example containing the " $\mathrm{Sm}(\mu-\mathrm{OC}) \mathrm{Mo}$ " fragment.

Keywords: Samarium; Carbonyl; Molybdenum; Crystal structure

## 1. Introduction

There is considerable current interest in heterobimetallic complexes due to the search for homogeneous counterparts of Fischer-Tropsch catalysis [1-14]. In this context, the preparation and chemistry of complexes containing lanthanide and late d-block transition metal (LTM) have atracted appreciable attention. To date, many different types of LTM complex have been synthesized, and most of them have been structurally characterized [15-21]. Of LTM complexes, those with d-block transition metal carbonylate moiety are the predominant majority. Structurally characterized examples include: $\left[(\mathrm{ErOH})\left(\mathrm{H}_{2} \mathrm{O}\right)_{4} \mathrm{Er}\left(\mathrm{Mo}(\mathrm{CO})_{3}\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)\right)_{3}\right]$ [19]. [(HMPA) $\mathrm{Yb}\left((\mu-\mathrm{OC}) \mathrm{Mo}(\mathrm{CO})_{2}\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)\right)_{2}$ [21], [(HMPA) $\mathrm{Yb}(\mu-\mathrm{OC}) \mathrm{Mo}(\mathrm{CO})_{2}\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)$ II $\left(\mathrm{C}_{5} \mathrm{H}_{5}\right) \mathrm{Mo}-$ (CO) $3_{2} \cdot \operatorname{THF}[21],\left[\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}(\mu-\mathrm{OC})_{2} \mathrm{Fe}\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)\right]_{2}$ [22], $\left[\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Yb}(\mu-\mathrm{OC}) \mathrm{Co}(\mathrm{CO})_{3}(\mathrm{THF})\right] \quad[23]$, $\left[\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Yb}\right]_{2}\left[\mathrm{Fe}_{3}(\mathrm{CO})_{11}\right] \quad[24] . \quad\left[\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Yb}(\mu-\right.$ $\left.\mathrm{OC})_{2} \mathrm{Mn}(\mathrm{CO})_{3}\right]_{2} \quad[25]$, $\left[\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Yb}(\mu\right.$ $\mathrm{OC})_{3} \mathrm{Mn}(\mathrm{CO})_{2} \mathrm{l}_{x} \quad[25]$, $\left[\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Yb}_{2}\left[\mathrm{Co}_{3}-\right.\right.$ $\left.\left(\mathrm{C}_{3} \mathrm{H}_{4} \mathrm{SiMe}_{3}\right)_{2}\left(\mu_{3}-\mathrm{CO}\right)_{4}\right][26]$ and (THF) ${ }_{5} \mathrm{La}[(\mu-\mathrm{OC})-$ $\left.\mathrm{Mo}(\mathrm{CO})_{2}\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)\right]_{3} \cdot \mathrm{THF}$ [27]. All of them consist of a transition metal carbonyl fragment and a lanthanide moiety bridged together via $\mathrm{Ln}-\mathrm{O}-\mathrm{C}-\mathrm{M} \quad(\mathrm{Ln}=$

[^0]lanthanide and $\mathbf{M}=$ transition metal) isocarbonyl linkages. All the above complexes containing ytterbium metal were prepared by redox reaction involving divalent ytterbium species and corresponding metal carbonyl compounds. As divalent samarium derivatives are stronger reducing agents and more oxophilic compared with the corresponding divalent yiterbium compounds. however, there are very few similar molecular structures containing samarium [22]. Herein, we report an example of a molecular structure containing " $\mathrm{Sm}=\mathrm{O}=\mathrm{C}-\mathrm{Mo}$ " isocarbonyl linkage.

## 2. Experimental details

All manipulations were routinely conducted under a dinitrogen atmosphere using the vacuum line technique unless otherwise indicated. Solvents were thoroughly dried over sodium benzophenone ketyl and distilled under nitrogen immediately prior to use. Reagents $\mathrm{Mo}(\mathrm{CO})_{6}$ and $\mathrm{C}_{5} \mathrm{Me}_{5} \mathrm{H}$ were purchased from the Aldrich Chemical Co. and used as received. Compounds $\left[\left(\mathrm{C}_{5} \mathrm{H}_{5}\right) \mathrm{Mo}(\mathrm{CO})_{3}\right]_{2} \mathrm{Hg}$ [28], $\mathrm{SmI}_{2}(\mathrm{THF})_{x} \quad$ [29] and $\mathrm{KC}_{5} \mathrm{Me}_{5}$ [30] were prepared by the published procedures. IR spectra were recorded on a Biorad FTS-7 IR spectrophotometer and ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra on a Jeol GSX 270 FT spectrometer with $\mathrm{Si}\left(\mathrm{CH}_{3}\right)_{4}$ as references.

### 2.1. Synthesis of $\left((T H F)_{4} I_{2} \operatorname{Sm}(\mu-\mathrm{OC}) \mathrm{Mo}\left(\mathrm{CO}_{2}\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)\right]\right.$ 1

A powder of $\mathrm{Hg}\left[\mathrm{Mo}(\mathrm{CO})_{3}\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)\right]_{2}(0.24 \mathrm{~g}, 0.348$ mmol) was added to the solution of $\mathrm{SmI}_{2}$ in THF ( 0.1 M, 7 ml ) with vigorous stiring at room temperature. The dark blue solution turned yellow in seconds and mercury metal droplets were observed. The reaction was stirred overnight. A bright yellow solution was obtained after removing the insoluble materials by centrifugation. Orange powder was isolated after evaporating all solvent in vacuo in ca. 70\% yield based on $\mathrm{Hg}\left[\mathrm{Mo}(\mathrm{CO})_{3}\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)\right]_{2}$. IR (Nujol mull on NaCl ): 2027 (s) and $1942(\mathrm{vs}) \mathrm{cm}^{-1}$. Crystals suitable for X-ray analysis were grown from saturated THF solution at $-20^{\circ} \mathrm{C}$.

### 2.2. Synthesis of $\left(\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right) \mathrm{MolCO}\right)_{3} \mathrm{I}_{2} \mathrm{Hg}_{5}$

This compound was prepared by the procedure of King and Stone [28] by substituting $\mathrm{C}_{5} \mathrm{Me}_{5} \mathrm{~K}$ for $\mathrm{C}_{5} \mathrm{H}_{3} \mathrm{Na}$ in ca. $70 \%$ yield based on $\mathrm{C}_{5} \mathrm{Me}_{5} \mathrm{~K}$. IR (Nujol mull on NaCl ): 1947(vs), $1889(\mathrm{sh})$ and $1873(\mathrm{vs}) \mathrm{cm}^{-1}$. ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): 1.57 \mathrm{ppm}\left(\mathrm{s}, \mathrm{CH}_{3}\right)$. ${ }^{13} \mathrm{C}$ NMR ( $\mathrm{CDCl}_{3}$ ): $11.73 \mathrm{ppm}\left(\mathrm{s}, \mathrm{CH}_{3}\right), 104.13 \mathrm{ppm}$ (s, ring carbons).

### 2.3. Preparation of $\left(\left(\mathrm{C}_{3} \mathrm{Me}_{s}\right) \mathrm{Mo}(\mathrm{CO})_{3}\right)_{2} 2$

A powder of $\left[\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right) \mathrm{Mo}(\mathrm{CO})_{3}\right]_{2} \mathrm{Hg}(0.208 \mathrm{~g}, 0.25$ mmol ) was added to the solution of $\mathrm{SmI}_{2}(0.1 \mathrm{M}, 5 \mathrm{ml})$ in THF at room temperature. The mixture was stirred overnight. A transparent orange solution was obtained after removing insoluble mercury by centrifugation. After evaporating all solvent, an oily residue was left. Extraction with 10 ml of dimethoxyethane (DME) pro-

ceeded to give a red solution. The single crystals of $\left[\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right) \mathrm{Mo}(\mathrm{CO})_{3}\right]_{2}$ suitable for X-ray analysis were grown from this solution at $-25^{\circ} \mathrm{C}$ in $30 \%$ yield based on $\left[\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right) \mathrm{Mo}(\mathrm{CO})_{3}\right]_{2} \mathrm{Hg}$.

## 2.4. $X$-ray analyses of complexes 1 and 2

Both orange block crystals of complex 1 and red plate crystals of complex 2 were mounted in glass capillaries under deoxygenated paraffin oil. Crystal intensity data were collected at ambient temperature on a Rigaku AFC7R diffractometer using Mo $\mathrm{K} \boldsymbol{\alpha}$ radiation.
( $\lambda=0.71073 \AA$ ). The data were corrected for Lorentz and polarization effects and absorption by the $\psi$ scan method [31]. Structures were solved by direct methods (SIR 88) [32] and refined by full-matrix least-squares analysis. Hydrogen atoms were placed at idealized positions and included in structure factor calculations but not refined. All calculations were performed on a Sili-con-Graphics computer using the TeXsan package from MSC [33].

The pertinent crystallographic data for both 1 and 2 are listed in Table 1. Coordinates of non-hydrogen atoms and selected bond distances and angles in 1 and 2 are summarized in Tables 2, 3, 4 and 5 respectively. Complete lists of bond lengths and angles and tables of hydrogen atom coordinates have been deposited at the Cambridge Crystallographic Data Center.

## 3. Results and discussion

Samarium diiodide is a strong one-electron reducing agent. There have been intensive investigations on its application in organic synthesis [ $29,34,35]$. Interactions of $\mathrm{SmI}_{2}$ with transition metal complexes very often lead to redox reaction rather than formation of heterobimetallic complexes. Evans et al. [36] reported the reaction of $\mathrm{SmI}_{2}(\mathrm{THF})_{3}$ with $\mathrm{Co}_{2}(\mathrm{CO})_{8}$ to give the $\left[(\mathrm{THF})_{5}\right.$. $\left.\mathrm{SmI}_{2}\right]^{+}\left[\mathrm{Co}(\mathrm{CO})_{4}\right]^{-}$ion pair instead of the bimetalitic compound $\left[(\mathrm{THF})_{8} \mathrm{I}_{2} \mathrm{Sm}(\mu-\mathrm{OC}) \mathrm{Co}(\mathrm{CO})_{3}\right]$.

The reaction of $\mathrm{SmI}_{2}(\mathrm{THF})_{s}$ with $\left[\left(\mathrm{C}_{5} \mathrm{H}_{5}\right) \mathrm{Mn}\right.$ (CO) $3_{2} \mathrm{Hg}$ is rapid and gives only one isolated product $\left[(\mathrm{THF})_{4} \mathrm{I}_{2} \mathrm{Sm}(\mu-\mathrm{OC}) \mathrm{Mo}(\mathrm{CO})_{2}\left(\mathrm{C}_{9} \mathrm{H}_{5}\right)\right] 1 \mathrm{in}$ high yield. Complex 1 is exceedingly air- and moisture-sersitive. It

Fig. 1. A perspective view of the structure of $\left[(\mathrm{THF})_{4} \mathrm{I}_{2} \mathrm{Sm}(\mu\right.$ $\left.\mathrm{OC}) \mathrm{Mo}(\mathrm{CO})_{2}\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)\right]$ I with atomic numbering scheme.
has been characterized by both spectroscopic and crysrallographic methods. A perspective view of complex 1 is presented in Fig. 1. The central samarium atom is coordinated to five oxygen atoms, of which four come from THF molecules and one isocarbonyl ligand. Together with two iodide ligands, they form a pentagonalbipyramidal structure surrounding the samarium atom with the oxygen atoms in the equatorial pentagonal plane and the iodide ligands in two apical positions. The average bond distances $\mathrm{Sm}=1[3.048(2) \AA]$ and $\mathrm{Sm}=$ O(THF) $[2,45(2) \AA]$ are significantly shorter than the corresponding average bond distances in complexes SmI , (THF) (DME), [3.246(1) and 2.530(5) A] and Smt ${ }_{2}^{2}(T H F)_{3}$ (DME) [ $3.233(1)$ and $\left.\left.2.571(4) \AA\right)\right][37]$. which provides further evidence that the samarium ion in 1 is trivalent. The five oxygen atoms and $\mathrm{Sm}^{1+}$ are almost coplanar, with maximum deviation $0.08 \AA$. The $t=S m=1$ angle is essentially linear $\left[174.35(8)^{\circ}\right]$, and 10 $1-5 m=0$ angles fall into a narrow range of $86.6(4)^{\circ}=$ $94.6(4)^{9}$, close to $90^{\circ}$. The five $\mathrm{O}-\mathrm{Sm}-\mathrm{O}$ angles for adjacent oxygen atoms are in the range $70.8(5)^{\circ}-$ $73.8(5)^{\circ}$, with mean value $72.04^{\circ}$. The bond distance $\mathrm{Sm}-\mathrm{O}(5)$ [isocarbonyl $2.41(2) \mathrm{A}$ ] is slightly shorter than other bond distances $\mathrm{Sm}=\mathrm{O}(1-4)$ [ranging from 2.42(2)
to $2.49(2) \AA$, average value $2.45(2) \AA$ ], and the distance $\mathrm{C}(17)-\mathrm{Mo}(1)$ [1.82(3) $\AA$ ] is also shorter than $\mathrm{C}(19)-$ $\operatorname{Mo}(1)$ [1.91(3) $\AA$ ] and $\mathrm{C}(18)-\mathrm{Mo}(1)$ [1.93(3) $\AA]$. The distance $O(5)-C(17)[1.22(2) \AA]$ is elongated compared with $C(18)-O(6)[1.14(3) \AA]$ and $C(19)-O(7)[1.17(3)$ $\AA$ ]. This suggests weakening of the CO bond upon coordination to both samarium and molybdenum centers. Similar observations have been made in other complexes containing an isocarbonyl linkage [3,27]. The distance $\mathrm{O}(5)-\mathrm{C}(17)$ is also slightly longer than the corresponding bond distances in [(HMPA) $\mathrm{Yb}[(\mu-\mathrm{OC})$ $\left.\mathrm{Mo}(\mathrm{CO})_{2}\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)\right]_{2} 3$ [mean value 1.17(3) A] and $\left[\mathrm{Yb}(\mathrm{HMPA})_{3}(\mu-\mathrm{OC}) \mathrm{Mo}(\mathrm{CO})_{2}\left(\mathrm{C}_{5} \mathrm{H}_{5}\right) \mathrm{I}\left(\mathrm{C}_{5} \mathrm{H}_{5}\right) \mathrm{Mo}-\right.$
$\left.(\mathrm{CO})_{3}\right]_{2} \cdot$ THF $4[1.15(3) \AA]_{\text {, probably because of the }}$ stronger oxophilicity of $\mathrm{Sm}^{3+}$ in 1 than that of the Yb ion in 3 and 4.

To investigate if this method is applicable to other Cp derivatives, we have prepared the compound $\left[\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right) \mathrm{Mo}(\mathrm{CO})_{3}\right]_{2} \mathrm{Hg}$ by a modified procedure [28] and studied its reaction with $\mathrm{SmI}_{2}(\mathrm{THF})_{x}$. However, the reaction is relatively slow and gives [( $\left.\mathrm{C}_{5} \mathrm{Me}_{5}\right)$ $\left.\mathrm{Mo}(\mathrm{CO})_{3}\right]_{2} 2$ in moderate yield ( $30 \%$ ) instead of the expected isocarbonyl linked analog of 1 . The homogeneity of bulk material in 2 was checked by solution IR spectroscopy. The complex 2 has been synthesized through rewcting $\left[\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right) \mathrm{Mo}(\mathrm{CO})_{2}\right]_{2}$ with carbon monoxide in isooctane solution [38]. However, its crystal and molecular structure remain unknown. Therefore. single crystals of 2 have been subjected to Xray analysis.

As shown in Fig. 2, the molecular geometry con involve a preudosquare-pyramidal configuration with the $\mathrm{C}_{5} \mathrm{Me}_{5}$ ring occupying the upical position and three carbonyl ligands and the metal=metal bond completing the square base. The dimer is related by a crystallo. graphic inversion center which requires an anfi rotational configuration between the two " $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)$. $\mathrm{Mo}(\mathrm{CO})_{3}$ " units. "The structural parameters of 2 are essentially identical to those in $\left[\left(\mathrm{C}_{5} \mathrm{H}_{5}\right) \mathrm{Mo}(\mathrm{CO})_{3}\right]_{2}[39]$, except for a slightly longer Mo-Mo distance (3.284(1) $\AA$ for 2, 3.235(1) $\AA$ for $\left.\left[\left(\mathrm{C}_{5} \mathrm{H}_{5}\right) \mathrm{Mo}(\mathrm{CO})_{3}\right]_{2}\right)$ and a small difference in the $\mathrm{C}(1)-\mathrm{Mo}(1)-\mathrm{C}(3)$ angle (113.5(3) in

Fig. 2. The molecular structure of $\left[\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right) \mathrm{Mo}(\mathrm{CO})_{3}\right]_{2} 2$ with atomic numbering scheme.
2. $105.9(1)^{\circ}$ in $\left.\left[\left(\mathrm{C}_{5} \mathrm{H}_{5}\right) \mathrm{Mo}(\mathrm{CO})_{3}\right]_{2}\right)$. The formation of 2 probably occurs via the combination of " $\left[\left(\mathrm{C}_{5} \mathrm{H}_{5}\right) \mathrm{Mo}\right.$ ( CO$)_{3} 3^{\prime \prime}$ radicals generated by the reduction. However, the marked difference in reactivity between $\left[\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)\right.$. $\left.\mathrm{Mo}(\mathrm{CO})_{3}\right]_{2} \mathrm{Hg}$ and $\left[\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right) \mathrm{Mo}(\mathrm{CO})_{3}\right]_{2} \mathrm{Hg}$ is not fully understoos.
