Abstract

Treatment of N-(2-chlorobenzylidene)-N, N'-dimethylethylenediamine, 2-CIC, H4C(H)=NCH2CH3NMe3, with tris(dibenzylideneacetone)dipalladium(0) in chloroform gave the oxidctive addition cyclometallated product [Pd(C,H,C(H)=NCH2CH2NMe2)(CI)] (1) with the palladium atom bonded to a C,N,N' terdentate donor ligand. Treatment of I with tertiary monophosphines gave the cyclometallated complexes $\left[Pd\left[C_{6}H_{4}C(H)=NCH_{2}CH_{2}NMe_{2}\right](CI)(L)\right]$ (2: L = PPh₃; 3: L = PEtPh₂; 4: L = PEt₂Ph; 5: L = PEt₃), where the phosphine ligand is either trans to the phenyl carbon atom (2, 3) or trans to the imine nitrogen atom (4, 5). Treatment of 1 with silver perchlorate followed by reaction with tertiary monophosphines gave the cyclometallated complexes [$\dot{Pd}(C_6H_4C(H)=\dot{N}-CH_2CH_2NMe_3)(L)ICIO_4$] (6: L = PPh; 7: L = PEtPh; 8: L = PEt; Ph; 9: L = PEt;). Reaction of 1 with thallium acetylacetonate gave the cyclometallated complex [Pd(C6H3C(H)=NCH3CH3NHe3(H3CCOCHCOCH3)] (10). Treatment of 1 with ditertiary diphosphines in a complex 1/diphosphine 2:1 molar ratio gave the dinuclear cyclometallated complexes [[Pd[C₆H₄C(H)=NCH₂CH₂NMe₂](CI)]₂(L-L)] (11: L-L = trans-Ph2PCH=CHP-Ph2; 12: L-L = Ph2P(CH2)3PPh2; 13: L-L = Ph2P(CH2)4PPh2), where the phosphorus atom is trans to the phenyl carbon atom. Treatment of 1 with silver perchlorate followed by ditertiary diphosphines in a complex 1/diphosphine 2:1 molar ratio gave the dinuclear cyclometallated complexes [{Pd[C6H,C(H)=NCH2CH2NMe2]]2(L-L)][ClO1]2 [14: L-L = trans-Ph2P-CH=CHPPh₂; 15: L-L = Ph₂P(CH₂)₃PPh₂; 16: L-L = Ph₂P(CH₂)₄PPh₂)]. Reaction of I with ditertiary diphosphines in a complex $\frac{1}{diphosphine}$ 1:1 molar ratio, and silver perchlorate as appropriate, <u>gave</u> the cyclometallated complexes [Pd(C₆H₄C(H)=NCH₂CH₂NMe₂KPh₂P(CH₂)₂PPh₂-P, P)][ClO₄] (17), [Pd(C₆H₄C(H)=NCH₂CH₂NMe₂KPh₂P(CH₂)₃PPh₂-P(CH₂)₄PCH₂)₄PCH₂ (17), [Pd(C₆H₄C(H)=NCH₂CH₂)(H) = NCH₂CH₂NMe₂KPh₂P(CH₂)₄PCH₂)₄PCH₂ (17), [Pd(C₆H₄C(H)=NCH₂CH₂)(H) = NCH₂CH₂NMe₂KPh₂P(CH₂)₄PCH₂ (17), [Pd(C₆H₄C(H)=NCH₂CH₂)(H) = NCH₂CH₂NMe₂KPh₂P(CH₂)₄PCH₂ (17), [Pd(C₆H₄C(H)=NCH₂CH₂)(H) = NCH₂CH₂ (17), [Pd(C₆H₄C(H)=NCH₂)(H) = NCH₂CH₂ (17), [Pd(C₆H₄C(H)=NCH₂)(H) = NCH₂CH₂ (17), [Pd(C₆H₄C(H)=NCH₂)(H) = NCH₂ (17), [Pd(C₆H₄C(H)=NCH₄)(H) = NCH₄ (17), [Pd(C₆H₄C(H)=NCH₄ $P, P) [Clo_{4}] (18), [Pd(C_{6}H_{4}C(H)=NCH_{2}CH_{2}NMe_{2}](cis-Ph_{2}PCH=CHPPh_{2}-P, P)[[Cl]] (19) and [Pd(C_{6}H_{4}C-P)[[Cl]] (19) and [Pd(C_{6}H_{4}C-P)[[Cl]] (19) [Pd(C_{6}H_{$ $(H) = NCH_2CH_2NMe_2 (CI)(Ph_2P(CH_2)_4PPh_2P, P) (20).$

Keywords: Palladium; Cyclometallation; Schiff base; Tertiary phosphine: Oxidative addition

1. Introduction

Cyclometallation is an important part of organometallic chemistry and various reviews covering this area have appeared [1]. Cyclometallated compounds show important applications, such as their use in regiospecific organic and organometallic synthesis [2,3] and in insertion reactions [4,5]. Bidentate nitrogen donor ligands which may undergo double cyclometallation to give compounds with two σ M-C bonds and with coordinations (4,5).

dination of each nitrogen atom to one of the metal centers have been reported. To name but a few, N, N, N', N'-tetraethyl para-xylene- α, α' -diamines [6], azines [7], diphenylpyrazines [8], diphenylpyrazines [9], benzylidenehydrazones [10], and bis(N-benzylidene)-1,4-phenylenediamines [11] always give doubly cyclometallated complexes; when Schiff bases derived from dialdehyde were used in cyclometallation reactions, mono- or dicyclometallated compounds could be obtained [12,13]. More recently we have become interested in bidentate and terdentate ligands which coordinate othe metal center through two donor atoms simultaneously, giving compounds with two fused five-

membered rings at palladium or platinum(II) [14]; the synthesis of these complexes is achieved via an oxidative addition process. Oxidative addition by halogenated Schiff bases has been used before as a means to obtain cyclometallated compounds [15-17]. An interesting feature of these compounds is that in the metallation process of the ligands, mononuclear species are produced, as opposed to the dinuclear complexes which are usually obtained when mono- and bidentate Schiff bases are reacted with palladium(II) acetate. In the former case, the cyclopalladated or cycloplatinated starting materials show a greater versatility towards reactions with neutral or anionic ligands, e.g. with Lewis bases such as tertiary phosphines or diphosphines, which may vary their coordination site in the complex, whereas in the latter one, this is more unlikely, probably as a consequence of the dimeric nature of the starting materials. This is one of the features we have encountered upon studying cyclometallation reactions of halogenated organic ligands and the results described in this paper show that the coordination position of the phosphine ligand depends on the synthetic conditions employed. In the present paper we report the intramolecular oxidative addition of N-(2-chlorobenzylidene)-N, N'-dimethylethylenediamine (this ligand has been used earlier in oxidative addition reactions involving platinum; see Ref. [17]) to tris(dibenzylideneacetone)dipalladium(0) to yield the cyclometallated complex 1 with two fused rings at palladium and subsequent reactions of 1 with phosphine or diphosphine ligands in different reaction conditions. The reaction of 1 with thallium acetylacetonate is also described.

2. Results and discussion

For the convenience of the reader the compounds and reactions are shown in Schemes 1 and 2. The compounds described in this paper were characterised by elemental analysis and by IR spectroscopy (data in Section 3) and by 'H and ³¹Pc¹H (Table 1) and (in part) ³²C NMR spectroscopy (Section 3).

The oxidative addition reaction of N-(2-chlorobenzyiidene)-N, N'-dimethylethylenediamine, 2-ClC₆H₄C(H)=NCH₂CH₂NMe₂, with tris(dibenzylideneacetone)dipalladium(0) in benzene gave the palladium(11) mononuclear cyclometallated complex [Pd[C₆H₄C(H)=NCH₂CH₂NMe₂](Cl)] (1), in 60% yield, which was fully characterized. The ¹H NMR spectrum showed well-defined 'virtual triplet' patterns at δ 3.68 and δ 2.89 ppm, for the =N-CH₂ and CH₂-NMe₂ protons respectively, with N = 12 Hz; a singlet at δ 2.67 ppm (6H) was assigned to the methyl protons. The NMe₂ resonance was shifted to higher frequency, showing palladium coordination to the amine nitrogen atom. A singlet at δ 7.52 was assigned to the HC=N proton, shifted to lower frequency on palladium-nitrogen coordination [18].

The ¹³C NMR spectrum showed resonances at δ 172.2 (C=N), δ 150.2 (C6), δ 158.0 (C1) and δ 48.3 (NMe₃); the former two were shifted to higher frequency by 13.3 and 26.9 ppm respectively from those for the free ligand, confirming that metallation had taken place [19]. The C1 resonance was also shifted to higher frequency, as expected. The two methylene resonances were separated by ca. 10 ppm, due to coordination of the amine nitrogen to the metal atom (vide infra). There was no noticeable quadrupolar broadening of these resonances with the ¹⁰⁵Pd (22% natural abundance, l = 5/2) nucleus.

The IR spectrum (see Section 3) showed a band at 1616 cm^{-1} , shifted to lower wavenumbers, consistent with palladium coordination to the nitrogen atom [20,21].

Treatment of 2-CIC₆H₄C(H)=NCH₂CH₂NMe₂ with palladium(II) acetate gave reduction to Pd(0); no oxidative addition of C-CI bonds to metallic palladium was observed, as has been described before [16]. Reaction of 2-CIC₆H₄C(H)=NCH₂CH₂NMe₂ with Li₂[PdCl₄] did not yield any :yclometallated product.

Treatment of 1 with tertiary phosphines gave the mononucler cyclometallated complexes $[Pd(C_6H_4C(H)=NCH_2CH_2NMe_2)(CI)(L)]$ (2: L = PPh₃; 3: L = PEtPh₂; 4: L = PEt₂Ph; 5: L = PEt₃) respectively, and treatment of 1 with silver perchlorate, followed by tertiary phosphines, gave the mononuclear cyclometallated complexes $[Pd(C_6H_4C(H)=NCH_2)]$

Scheme 1. (i) 1/2 [Pd₂(dba)₃]; (ii) lequiv. of L; (iii) AgClO₂ followed by lequiv. of L; (iv) Tl(acac).

Scheme 2. (i) L; (ii) AgClO₄ followed by L; (iii) AgClO₄ followed by L; (iv) cis-dppe in acetone; (v) dppb in acetone.

 $CH_{1}NMe_{2}(L)$ [CIO₄] (6: L = PPh₃; 7: L = PEtPh₂; 8: $L = PEt_{1}Ph; 9: L = PEt_{1}$) respectively, which were fully characterised (see Section 3 and Table 1). Electric conductivity measurements in dry acetonitrile solution showed complexes 6-9 to be 1:1 electrolytes [22] (see Section 3). In complexes 2 and 3 no coupling of the HC=N and H5 proton resonances to the ³¹P nucleus was observed; also, the =NCH₂ resonance was not coupled to the ³¹ P nucleus. However, in complexes 4 and 5 the HC=N, H5 and $\delta = NCH_2$ proton resonances were coupled to the ³¹P nucleus, as corresponds to the phosphine ligand being cis to the metallated carbon atom. We and others have observed that, in cyclometallated palladium(II) compounds of Schiff bases with only one tertiary monophosphine coordinated to the metal center, this ligand usually shows a trans geometry with respect to the imine nitrogen atom [16, 23-27]; we have also found that the HC=N and H5 proton resonances are always coupled to the ³¹P nucleus, except when the Pd \leftarrow N bond was cleaved. Coupling of the H5 resonance to the ^{3t} P nucleus trans to carbon has been observed in complexes with chelating diphosphines; in this case there could be coupling through the carbon chain between the phosphorus atoms [28,29]. However, even in these cases no coupling between the HC=N nucleus to the ³¹ P nucleus *trans* to carbon was detected (vide infra). In the present case we tentatively attribute these findings to different coordination sites of the phosphine ligand in compounds 2, 3 on the one hand (P trans to C), and of compounds 4, 5 on the other hand (P trans to N), in spite of the fact that the ³¹P resonance shows a rather high value in compounds 2 and 3 for phosphorus trans to a phenyl carbon atom as compared to values found previously [25] (Table 1). We suggest that the phosphine ligand produces cleavage of the Pd ← NMe₂ bond with coordination of the phosphorus atom to the vacant site at palladium, trans to the phenyl carbon atom. This coordination prevails with the less basic phosphines, i.e. PPh3, PEtPh2 and the diphosphines trans-dppe, dppe and dppb. However, with the more basic phosphines, i.e. PEt₂Ph and PEt, palladium coordination is rearranged to give complexes with the phosphine ligand trans to the imine nitrogen atom. This could be related to the *m*-acceptor properties of the phosphine ligands. We treated com-pound 1 with 2 mol of PPh₃ and the ¹H and ³¹P NMR results show that the phosphine ligands are mutually trans (only one singlet is observed in the ³¹P NMR) as we have observed before [25]; again there is a change in the coordination site of the ligand initially trans to the phenyl carbon atom. H NMR data: $\delta(HC=N)$ 8.20, δ(H2) 7.25d, δ(H3) 6.87t, δ(H4) 6.51t, δ(H5) 6.42d, δ (NCH₂CH₃) 4.06, 2.82 N = 12.8 Hz, δ (NMe₂) 2.91 ppm. ³J(H2H3) 7.3, ³J(H3H4) 7.4, ³J(H4H5) 7.4 Hz. ³¹ P NMR & 27.3 ppm.] Furthermore, when the chloride ion is removed by the silver salt, this leaves a vacant position at palladium trans to the imine nitrogen atom, which renders the phosphine ligand trans to nitrogen in all cases (compounds 6-9 and 14-16). The δMe_{2} resonance in the ¹H NMR spectrum for compounds 2-5 lies ca. δ 2.30 ppm as corresponds to the non-coordinated NMe₂ group (cf. δ 2.31 ppm for the free ligand); for compounds 6-9 values close to δ

2.70 ppm would be expected (cf. δ 2.67 ppm for 1), however the δMe_2 resonance appears in the range δ 2.16-2.02 for compounds 6-8 and at δ 2.74 ppm for

compound 9. We suggest the lower δ value observed for the δ Me₂ resonance in 6-8 is due to shielding of a phosphine phenyl ring; as proof, in the compound with triethylphosphine, 9, the δ Me₂ resonance appears at δ 2.74 ppm. The separation of the N(CH₂)₂ resonances in the ¹⁵C NMR spectra of compounds 6-9, ca. 10-15 ppm, shows coordination of the NMe₂ group to the metal atom, as opposed to compounds 2, 3, 5, where it is ca. 4-7 ppm.

The ³¹ P(¹ H) NMR spectra show a singlet resonance for the phosphorus nucleus in 2–5 and 6–9; substitution of the phosphine phenyl groups for ethyl groups shifts the ³¹ P resonance to lower frequency (Table 1). Comparison of the difference in the ³¹ P chemical shift values for pairs of compounds bearing the same phosphine ligand, $\Delta \delta$, showed the resonances for compounds 6–9 to be at lower frequency than those for 2–5 in all cases (Table 1). However, $\Delta \delta$ is greater when the ³¹ P nucleus is always *trans* to nitrogen [$\Delta \delta(4,8) = 8.86$ ppm; $\Delta \delta(5,9) = 7.0$ ppm] than when the ³¹ P nucleus is *trans* to different atoms in the complexes, i.e. ³¹ P *trans* to carbon or nitrogen [$\Delta \delta(2,6) = 4.47$ ppm; $\Delta \delta(3,7) =$ 3.84 ppm].

Treatment of 1 with thallium: acetylacetonate gave the soluble complex $[Pd(C_{h}H_{c}(H)=NCH_{2}CH_{-}NMe_{2}](H_{3}CCOCHCOCH_{3})]$ 10 as an air-stable solid, which was fully characterized (see Section 3 and Table 1). The ¹H NMR spectrum showed singlet resonances at δ 5.37 and 2.03 ppm assigned to the C H and to the two C-Me groups respectively. The ¹³C NMR spectrum showed singlets at δ 100.65 and δ 23.03 ppm, assigned to the CH and C-Me resonances respectively.

Reaction of 1 with ditertiary diphosphines in a complex 1/diphosphine 2:1 molar ratio gave the dinuclear cyclometallated complexes [{Pd[C₆H₄C(H)=NCH₂-CH₂NMe₂](Cl)]₂(μ -Ph₂PRPPh₂)] [11: R = trans-CH=CH; 12: R = (CH₂)₃; 13: R = (CH₂)₄] respectively, and treatment of 1 with silver perchlorate followed by ditertiary diphosphines gave the dinuclear cyclometallated complexes [{Pd[C₆H₄C(H)=NCH₂CH₂NMe₂]}₂(μ -Ph₂PR- PPh_2)[[ClO₄]₂ [14: R = trans-CH=CH; 15: R = $(CH_2)_3$: 16: R = $(CH_2)_4$] respectively, which were fully characterised (see Section 3 and Table 1). Electric conductivity measurements in dry acetonitrile solution showed complexes 14-16 to be 1:2 electrolytes [22] (see Section 3). In the ¹H NMR spectra of compounds 11-13 singlets were observed for the HC=N and H5 resonances (Table 1); no coupling of the $\delta = NCH_2$ resonance to the ³¹P nucleus was observed. In view of this we tentatively assign these compounds the structures depicted in Scheme 2, with the phosphorus atom trans to the phenyl carbon atom of the metallated ring. There is only one set of resonances for each cyclopalladated moiety in the ¹H and ¹³C NMR spectra and only one singlet for the two ³¹P nuclei in the ³¹P(¹H) spectrum. This suggests that the compounds are centrosymmetric, as we have shown before in related compounds [30,31]. In the ¹H NMR spectra of complexes 11 and 14, apparent triplets at δ 6.75 and δ 8.30 ppm respectively were assigned to the PCH=CHP resonances (AA'XX' spin system) with N ca. 41 Hz. In the 'H NMR spectra of compounds 14-16 the NMe2 resonance is shifted to lower frequency from the expected position, ca. 2.7 ppm, due to shielding of the phosphine phenyl ring.

Treatment of 1 with ditertiary diphosphines in a complex 1/diphosphine 1:1 molar ratio, and silver perchlorate gave the mononuclear cyclometallated complexes [$\{P\bar{d}[C_6H_2C(H)=NCH_2CH_2NMe_2\}$]. (Ph_PRPPh_P.P.P)IClO_1 [17: R = (CH_2)_2; 18: R = (CH_2)_3] respectively (see Section 3 and Table 1). Electric conductivity measurements in dry acetonitrile solution showed the complexes to be 1:1 electrolytes [22] (see Section 3). When the reaction was carried out in the absence of the perchlorate salt, an untreatable mixture was obtained. However, when 1 was treated only with *cis*-dppe in a complex 1/diphosphine 1:1 molar ratio, the mononuclear cyclometallated complex [$[Pd[C_4H_2C(H)=NCH_2CH_NMe_2]](cis-Ph_2PCH=$ CHPPh_P.P.P)ICl] (19) was obtained, which was fully

characterised (see Section 3 and Table 1). Electric

^b In CDCl₃, unless otherwise stated. Measured at 250 MHz (ca. ±20°C), chemical shifts (b) in ppm (±0.01) to high frequency of SiMe₄.

Occluded by the phosphine resonances.

Notes to Table 1:

in CDCl₁. Measured at 100.6 MHz (ca. $\pm 20^{\circ}$ C); chemical shifts (δ) in ppm (± 0.1) to high frequency of 85% H₃PO₄.

^e Coupling constants in Hz.

^d s, singlet; d, doublet; dd, doublet of doublets; t, triplet; td, triplet of doublets; m, multiplet.

In acetone-d6.

[&]quot; "J(PP) values in parentheses.

conductivity measurements in dry acetonitrile solution showed the complex to be a 1:1 electrolyte (see Section 3). The ³¹P{¹H} NMR spectra showed two doublets for the two inequivalent phosphorus nuclei. The resonance at lower frequency was assigned to the phosphorus nucleus trans to the phenyl carbon atom in accordance with the higher trans influence of the latter with respect to the C=N nitrogen atom [32]. The HC=N resonance was only coupled to the ³¹P nucleus trans to nitrogen. In compound 17 the H5 proton was coupled to both ³¹P nuclei with ${}^{4}J(P_{trans-C}H) < {}^{4}J(P_{trans-N}H)$. This was confirmed by selective decoupling experiments on the ³¹P atoms. Although the NMe2 group is not coordinated to the metal atom, the methyl resonance was shifted to lower frequency due to shielding of the phenyl rings on the phosphorus atom trans to carbon.

Treatment of 1 with dpph in a complex 1/diphosphine 1:1 molar ratio gave the mononuclear cyclometallated complex [{PG[C₆H₄C(H)=NCH₂CH₂-NMe₃](CI){Ph₂PC(H₂)₄PPh₂-P,P] (20) which was fully characterized (see Section 3 and Table 1). Electric conductivity measurements in dry acetonitrile solution showed the compound to be a non-electrolyte. The Pd(PP)CI moiety can rotate about the Pd-C vector so that the palladium coordination plane is at 90° to the metallated phenyl ring, eliminating coupling between the ³¹P atom and the H5 or the HC=N protons [25]; also, no coupling of the =NCH₂ resonance to the ³¹P nucleus was observed. Both ³¹P resonances were inequivocally assigned (see above).

Garrou [33] has proposed that the ³¹P chemical shift is influenced by ring size. The data for compounds 17-19 are summarized in Table 2. We have calculated Δ_R for compounds for both phosphorus atoms *trans* to carbon and *trans* to nitrogen (see Table 2). In the five-membered ring cases (compounds 17, 19) the absolute value of Δ_R is smaller when the ³¹P nucleus is

Table 2

r para	114.1635			
	Pb	P _a	Δ_{R}	
17	31.78	59.09	27.31	
18	31.78	24.38	- 7.40	
19	31.78	60.29	28.51	
	P۴	Pb	$\Delta_{\rm R}$	
17	30.79	41.08	10.29

^a P_a phosphorus *trans* to nitrogen. P_b phosphorus *trans* to carbon. ^b Equivalent phosphorus (-PPh₂) in a non-chelated analogue (compound 15).

² Equivalent phosphorus (-PPh₂) in a non-chelated analogue (compound 12). trans to carbon than to nitrogen; the reverse is true for the six-membered ring compound 18.

3. Experimental details

All reactions were carried out in an atmosphere of dry nitrogen. Solvents were purified by standard methods [34]. Chemicals were reagent grade. Tris(dibenzylideneacetone)dipalladium(0) and thallium acetylacetonate were purchased from Aldrich-Chemie. The diphosphines Ph2P(CH2)2PPh2 (dppe), Ph2P(CH2)3PPh2 (dppp) and Ph₂P(CH₂)₄PPh₂ (dppb) were purchased form Aldrich-Chemie; cis-Ph2PCH=CHPPh2 (cis-1,2dppe) and trans-Ph2PCH=CHPPh2 (trans-1,2-dppe) were prepared according to procedures described elsewhere [35]. Microanalyses were carried out at the Servicio de Análisis Elemental at the University of Santiago using a Carlo-Erba Elemental Analyzer. Model 1108. IR spectra were recorded as Nujol mulls or polythene discs on a Perkin-Elmer 1330 and on a Mattson (Servicio de Espectroscopía of the University of Santiago) spectrophotometers. NMR spectra were obtained as CDCl₃ or $(CD_3)_2CO$ solutions and referenced to $SiMe_4$ (¹H, ¹³C) or 85% H₃PO₄ (³¹P-(¹H)) and were recorded on Bruker WM-250, AMX-300 and AC-200 spectrometers. All chemical shifts were reported downfield from the standards

The synthesis of 2-ClC₆H₄C(H)=NCH₂CH₂NMe₂ was performed by heating a chloroform solution of the appropriate quantities of 2-chlorobenzaldehyde and N,N'-dimethylethylenediamine in a Dean-Stark apparatus under reflux. ¹³C(¹H) NMR (75.48 MHz, CDCl₃): δ 158.9 (C=N); δ 135.3 (Cl); δ 135.3 (C6); δ 131.7, δ 130.0, δ 128.6, δ 127.2 (C2, C3, C4, C5); δ 60.2, δ 60.1 (CH₂); δ 46.00 (NMe₂).

CAUTION Perchlorate salts of metal complexes are potentially explosive. Extreme caution should be exercised in handling this material.

3.1. Preparation of $[Pd[C_6H_4C(H) = NCH_2CH_2N-Me_2](Cl)]$ (1)

 $2-\text{ClC}_{6}H_{4}C(H)=\text{NCH}_{2}CH_{2}\text{NMe}_{2}$ (140 mg, 0.67 mmol) and tris(dibenzylideneacetone)dipalladium(0) (300 mg, 0.33 mmol) were added to 25 cm³ of benzene to give a dark red solution which was heated under reflux for 2h. After cooling to room temperature the solution was filtered to eliminate the small amount of black palladium formed. The solvent was removed under vacuum to give a yellow solid which was chromatographed on a column packed with silica gel. Elution with dichloromethane/ethanol (1%) afforded the final product as a pale yellow solid after concentration. Yield 60%. Anal. Found: C, 42.0; H, 4.7; N, 8.8, $C_{11}H_{15}N_2 CIPd Calc.: C, 41.7; H, 4.8; N, 8.8\%.
