ORGANOMETALLIC ANIONS CONTAINING ISONITRILE LIGANDS

II\*. THE SYNTHESIS AND REACTION CHEMISTRY OF CYCLOPENTA-  
DIENYLMOLYBDENUM DICARBONYLMETHYLISONITRILE ANION

Summary

The anion,  $(\eta^5\text{-C}_5\text{H}_5)\text{Mo}(\text{CO})_2\text{CNCH}_3^-$ , has been prepared and spectroscopically investigated. The results show that the isonitrile ligand readily and extensively engages in metal to ligand  $\pi$ -backbonding. This anion undergoes chemical reaction via halide displacements producing a variety of neutral complexes containing isonitrile ligands. In reactions with  $\text{CH}_2(\text{Cl})\text{CN}$ ,  $(\text{CH}_3)_3\text{GeBr}$ ,  $(\text{CH}_3)_3\text{SnCl}$ , and  $(\text{C}_6\text{H}_5)_3\text{PbI}$  in THF at  $-78^\circ$ , the compounds  $(\eta^5\text{-C}_5\text{H}_5)\text{Mo}(\text{CO})_2\text{-(CNCH}_3\text{)R}$  ( $\text{R} = \text{CH}_2\text{CN}$ ,  $\text{Ge}(\text{CH}_3)_3$ ,  $\text{Sn}(\text{CH}_3)_3$ , and  $\text{Pb}(\text{C}_6\text{H}_5)_3$ ) have been prepared. These results demonstrate the synthetic value of the new reagent.

---

Recent studies have shown isonitrile molecules to be unusually versatile ligands [2]. This undoubtedly arises from their ability to bond through both  $\sigma$ -donation and  $\pi$ -backbonding.

In an effort to further investigate the importance of the  $\pi$ -backbonding component we have initiated a study of organometallic anions which contain isonitrile ligands, in hopes of (1) obtaining some evidence as to the extent in which isonitrile ligands might engage in  $\pi$ -backbonding, and (2) generating suitable intermediates which might be valuable for further use in syntheses of isonitrile complexes. We report here the results of our studies of the anion  $(\eta^5\text{-C}_5\text{H}_5)\text{Mo}(\text{CO})_2\text{-CHCN}_3^-$  (I). Reduction of the complex  $(\eta^5\text{-C}_5\text{H}_5)\text{Mo}(\text{CO})_2(\text{CNCH}_3)\text{Cl}$  with  $\text{Na}(\text{Hg})$  in tetrahydrofuran at room temperature gives, upon filtration, a light yellow solution containing the anion I. This is supported by the PMR spectrum taken in tetrahydrofuran- $d_8$  which shows resonances at  $\tau$  5.05(5) ( $\text{C}_5\text{H}_5$ ) and 7.10(3) ( $\text{N-CH}_3$ ) ppm. The infrared spectrum (in THF) shows absorptions at 1710, 1765, and  $1875\text{ cm}^{-1}$ . The two lower energy absorptions may be assigned

to the CO stretches, and their low frequencies attest to the anionic character of the complex. The absorption at  $1875\text{ cm}^{-1}$  must be assigned to the CN stretching vibration, as there are no other absorptions observed in the multiple bond stretching region. The low frequency\* of this absorption also supports the anionic character of the complex, but more importantly indicates that the ligand is now extensively engaged in  $\pi$ -backbonding.

In addition, the anion has proven to be a very effective intermediate for use in the synthesis of a variety of isonitrile complexes. In reactions with the compounds  $\text{CH}_2\text{ClCN}$ ,  $(\text{CH}_3)_3\text{GeBr}$ ,  $(\text{CH}_3)_3\text{SnCl}$ , and  $(\text{C}_6\text{H}_5)_3\text{PbI}$  in tetrahydrofuran at  $-78^\circ$ , the compounds  $(\eta^5\text{-C}_5\text{H}_5)\text{Mo}(\text{CO})_2(\text{CHCN}_3)\text{R}$  ( $\text{R} = \text{CH}_2\text{CN}$ ,  $\text{Ge}(\text{CH}_3)_3$ ,  $\text{Sn}(\text{CH}_3)_3$ , and  $\text{Pb}(\text{C}_6\text{H}_5)_3$ ) have been prepared\*\*. Pertinent spectral and physical properties are listed in Table 1. As indicated by the infrared spectra, all compounds apparently exist as a mixture of *cis* and *trans* isomers [3].

Addition of deoxygenated acetic acid to solutions of the anion, followed by solvent evaporation and hexane extraction, yields yellow-brown crystals on cooling to  $-78^\circ$ . These can be dried at low temperature, but melt when warmed to room temperature. The PMR spectrum of this oil in benzene shows resonances at  $\tau$  5.15(5) ( $\text{C}_5\text{H}_5$ ); 7.83(3) ( $\text{CH}_3$ ); and 15.05(1) (H). The high field resonance is indicative of the Mo—H bond [4]. The infrared spectrum shows absorptions at 2136 (CN), 1963 (CO), and 1900 (CO)  $\text{cm}^{-1}$ , and strongly indicates formulation of the compound as  $(\eta^5\text{-C}_5\text{H}_5)\text{Mo}(\text{CO})_2(\text{CNCH}_3)\text{H}$ . The hydride is thermally unstable and undergoes complete decomposition in a few hours at room temperature to give mainly  $(\eta^5\text{-C}_5\text{H}_5)_2\text{Mo}_2(\text{CO})_5\text{CNCH}_3$  [5] and  $[(\eta^5\text{-C}_5\text{H}_5)\text{Mo}(\text{CO})_3]_2$ , in approximately a 3/1 ratio. We have not been able to identify the expected decomposition product,  $[(\eta^5\text{-C}_5\text{H}_5)\text{Mo}(\text{CO})_2(\text{CNCH}_3)]_2$ . It may be that this dimer is comparatively unstable and decomposes to the more stable unsubstituted and monosubstituted dinuclear species.
