#### Abstract

Chemoselective cross-metathesis reactions between methyl sorbate or 1,3 -dienic amides and various olefins in the presence of the Grubbs-Hoveyda catalyst have been investigated. Cross-metathesis reactions turned out to be more chemoselective with 1,3-dienic amides than with 1,3 -dienic esters. © 2006 Elsevier B.V. All rights reserved.

## 1. Introduction

In the last decade, metal-catalyzed olefin metathesis has emerged as one of the most powerful and reliable organometallic transformations for carbon-carbon bond formation in organic synthesis [1], and particularly, ring-closing metathesis (RCM) and cross-metathesis (CM) [2] reactions have been thoroughly investigated. These convenient synthetic techniques have recently gained prominence due to the commercial availability of molybdenum catalyst [Mo]-I [3] and robust ruthenium carbene complexes such as $[\mathrm{Ru}]$-I [4], [ Ru$]-$ II [5], and [Ru]-III [6], which exhibit good activities, operational simplicity, and remarkable functional group tolerance (Fig. 1). Therefore, the metathesis has become a powerful synthetic tool that has been widely used in the synthesis of natural products [7].

Although the RCM between 1,3-dienes and olefins has been used to synthesize complex naturally occurring molecules [8], CM reactions involving conjugated 1,3-dienes have been scarcely investigated [9]. Only recently, CM reac-

[^0]tions have been described between conjugated electrondeficient olefins such as ethyl sorbate and various olefin cross-partners [10]. When ethyl sorbate (1) and 5-hexenyl acetate (2) were heated in refluxing $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ in the presence of catalyst $[\mathrm{Ru}]$-II ( $10 \mathrm{~mol} \%$ ), 1,3-diene $\mathbf{3}$ and olefin $\mathbf{4}$ were obtained as an inseparable 4/1 mixture (Scheme 1). Indeed, the ester functionality in ethyl sorbate (1) does not sufficiently deactivate the $\alpha, \beta$-double bond towards CM and thus when $[\mathrm{Ru}]-\mathrm{II}$ is used, both olefins of the diene react. By reducing the electron density at the $\alpha, \beta$-double bond, as well as by increasing steric hindrance at the $\alpha$-carbon, the CM is more chemoselective [10].

As the phosphine-free ruthenium complex [Ru]-III exhibits superior activity towards electron-deficient olefins compared to [Ru]-II [11], we initiated a systematic study designed to explore the construction of substituted 1,3dienes of type $\mathbf{A}$ by performing CM reactions between methyl sorbate (5) and diverse olefin partners. Furthermore, we also investigated the corresponding dienic amides 14-16 in order to increase the chemoselectivity of the CM reaction, which would result in the selective formation of dienes of type $\mathbf{A}$ and therefore would decrease the formation of olefins of type $\mathbf{B}$ (Scheme 2).

## 2. CM reactions with methyl sorbate (5)

When methyl sorbate (5) and oct-1-ene (5 equiv.) were stirred in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at $\mathrm{rt}(c=0.2 \mathrm{M})$ for 48 h in the presence of $[\mathrm{Ru}]$-III ( $5 \mathrm{~mol} \%$ ), the desired conjugated diene 6 was isolated as an inseparable mixture of $(E, E)-6$ and $(E, Z)-6$ stereoisomers in a $10 / 1$ ratio, accompanied by the corresponding mono-olefin of type $\mathbf{B}(\mathbf{A} / \mathbf{B}=2.5 / 1)$ with a global yield of $68 \%$ (Table 1, entry 1). In the case of the CM between methyl sorbate (5) and allyl trimethylsilane, dienic ester 7 was obtained as a mixture of stereoisomers $(E, E)-7$ and $(E, Z)-7$ in a $5 / 1$ ratio in addition to being contaminated with olefin of type $\mathbf{B}(\mathbf{A} / \mathbf{B}=6 / 1)$. When styrene was used, the conjugated diene $\mathbf{8}$ was formed in $35 \%$ yield with an excellent stereoselectivity as only the $(E, E)-\mathbf{8}$ isomer was isolated and no trace of the mono-olefin of type B was observed (Table 1, entry 3) [12].

Other olefins such as diethyl allylphosphonate, allyl bromide and $N$-allyl- $p$-toluenesulfonamide were also examined in the cross-metathesis reaction with methyl sorbate (5). In each case, the corresponding CM products were formed in moderate yields ( $45-56 \%$ ) and were sometimes accompanied by the mono-olefin of type $\mathbf{B}$ (Table 1, entries 4-6) [12].

The CM reaction with electron-deficient olefins such as methyl vinyl ketone and tert-butyl acrylate was also studied and, respectively, afforded the CM products $\mathbf{1 2}$ and $\mathbf{1 3}$ in poor yields (13-30\%) (Table 1, entries 7 and 8 ) [12].

## 3. CM with dienic amides

It was hypothesized the kinetics of the CM reaction with $\alpha, \beta$-unsaturated amides was decreased by the chelation of the amide carbonyl group on the ruthenium center, and therefore, the efficiency of CM between $\alpha, \beta$-unsaturated amides and olefins was affected by the substituents on the amide nitrogen [13]. Since the dienic esters did not show good chemoselectivity in CM, we turned our attention to dienic amides possessing more electron-rich carbonyl groups. In the case of $(E, E)$-dienic amides, easily accessible from sorbic acid [14], the chelation as well as the steric hindrance should avoid the CM with the $\alpha, \beta$-unsaturation and the CM product at the $\gamma, \delta$-position should be obtained selectively. In consequence, CM reactions between dienic amides $\mathbf{1 4} \mathbf{- 1 6}$ with a variety of electron-rich olefins were examined. The results are reported in Table 2.

${ }^{\mathrm{a}}$ Isolated yield for the mixture of $\mathbf{A}$ and $\mathbf{B}$.
${ }^{\mathrm{b}}$ No trace of B was detected.
${ }^{\text {c }}$ A trienic compound was identified by GC/MS and NMR spectroscopy (see Section 5).

When the dienic $N, N$-diisopropylamide 14 was utilized in the CM reaction with oct-1-ene ( 5 equiv.) in the presence of $10 \mathrm{~mol} \%$ of [Ru]-III at rt for 24 h , the cross-metathesis product $\mathbf{1 7}$ was isolated in $36 \%$ yield in a $28 / 1(E, E) /(E, Z)$ ratio and no trace of mono-olefin of type $\mathbf{B}$ was detected (Table 2, entry 1). Under the same conditions (oct-1-ene, 5 equiv.; [ Ru ]-III $10 \mathrm{~mol} \%, \mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{rt}, 24 \mathrm{~h}$ ), the dienic Weinreb amide $\mathbf{1 5}$ was transformed into the dienic amide $\mathbf{1 8}[(E, E) /$ $(E, Z)=6 / 1]$ and into the corresponding mono-olefin of type B in $65 \%$ yield in a $3.5 / 1 \mathbf{A} / \mathbf{B}$ ratio (Table 2, entry 2 ). In order to decrease the formation of the mono-olefin of type $\mathbf{B}$, the amount of the [Ru]-III catalyst was decreased to $5 \mathrm{~mol} \%$. After 24 h , the dienic compound $\mathbf{1 8}$ and the mono-olefin of type $\mathbf{B}$ were obtained in $60 \%$ yield in a $5 / 1$ ratio, and under these conditions the $(E, E)-\mathbf{1 8} /(E, Z)-\mathbf{1 8}$ ratio was 29/1 (Table 2 , entry 3 ). It is worth noting that, when the reaction was stopped after 1 h , the $(E, E)-\mathbf{1 8}$ and $(E, Z) \mathbf{- 1 8}$ ratio was increased to $49 / 1$, the isolated yield of 18 along with the corresponding mono-olefin of type B was $64 \%$, and the $\mathbf{A} / \mathbf{B}$ ratio was interestingly increased to $13 / 1$ (Table 2, entry 4 ). Thus, the increase of the $\mathbf{1 8 A} / \mathbf{1 8 B}$ ratio by decreasing the reaction time seems to indicate that compound $\mathbf{1 8 B}$ would be formed from the putative kinetic diene 18A, which would imply an insertion of the $[\mathrm{Ru}]$ in its $\alpha, \beta$-double bond. To ver-
ify this hypothesis, compound 18A was treated with catalyst [Ru]-III ( $5 \mathrm{~mol} \%$ ) in the presence of 5 equiv. of oct-1-ene (Scheme 3) [15]. After 4.5 h a negligible amount of monoolefin 18B was formed, the main product of the reaction being dimer $\mathbf{C}$. After 24 h , the amount of dimer $\mathbf{C}$ increased without significant augmentation of the monoolefin 18B. However, at this stage, partial decomposition of 18A was ascertained. An additional amount of $5 \mathrm{~mol} \%$ of catalyst [Ru]-III was subsequently added and after 3 days of stirring diene $\mathbf{1 8 A}$ was almost totally decomposed and $\mathbf{1 8 B}$ was not formed anymore. So it seems that the decrease of the 18A/ 18B ratio by increasing the reaction time could be due to the decomposition of diene 18A. Furthermore, when 18A was stirred alone with catalyst [Ru]-III ( $10 \mathrm{~mol} \%$ ) for 24 h , only traces of 18B were detected and no significant decomposition of 18A occurred. However, as the formation of dimer $\mathbf{C}$ was noticed, it seems that catalyst [Ru]-III slowly inserts in the $\gamma, \delta$-double bond of diene 18A. According to these results, it seems that the main active species is intermediate $\mathbf{Z}$ which principally inserts in the $\gamma, \delta$-double bond of amide $\mathbf{1 5}$ to give 18A, and to a minor extent in the $\alpha, \beta$-double bond of 15 to give 18B. Finally, by decreasing the amount of catalyst [ Ru$]$-III and the reaction time, the chemoselectivity can be improved.

When allyl bromide was involved in the CM reaction with Weinreb amide $\mathbf{1 5}$, for 14 h at rt , with $5 \mathrm{~mol} \%$ of [ Ru$]$-III, the corresponding dienic amide 19 was formed in $39 \%$ yield with a very $\operatorname{good}(E, E) /(E, Z)$ ratio of $19 / 1$. Interestingly, no trace of mono-olefin of type $\mathbf{B}$ was detected (Table 2, entry 5). In the case of the CM reaction between Weinreb amide 15 and ( $Z$ )-1,4-dichloro-2-butene the best results were obtained when the reaction was carried out with $5 \mathrm{~mol} \%$ of [Ru]-III, at rt for 30 min . Under these conditions, compound 20 was isolated in $59 \%$ yield $[(E, E) /(E, Z)=32 / 1]$ with a $\mathbf{A} / \mathbf{B}$ ratio of $13 / 1$ (Table 2, entries 6 and 7). When amide $\mathbf{1 5}$ was involved in the cross-metathesis reaction with 1-acetoxy-but-3-ene, allyltrimethylsilane, and ( $Z$ )-1,4-diacetoxy-but-2-ene, the dienic cross-metathesis products were isolated as a mixture of $(E, E)$ - and $(E, Z)$-stereoisomers. In the case of the CM between amide 15 and 1-acetoxy-but-3-ene ( 24 h , $10 \mathrm{~mol} \%[\mathrm{Ru}]-\mathrm{III})$, compound 21 was obtained along with the corresponding mono-olefin of type $\mathbf{B}$ in a $24 / 1$ ratio and $46 \%$ overall yield. With allyltrimethylsilane, the cross-product 22 was isolated in $45 \%$ yield with a ( $E, E$ )22/( $E, Z$ )-22 ratio of $4 / 1$ and 23 was formed in $42 \%$ yield with a $(E, E)-23 /(E, Z)-23$ ratio of $5 / 1$ when $(Z)$-1,4-diacet-oxy-but-2-ene was used in the CM reaction with amide $\mathbf{1 5}$ (Table 2, entries 8-10). Interestingly in these three latter cases, the formation of $\mathbf{B}$ was probably kinetically decreased due to either a complexation of the ruthenium complex with participation of carbonyl group of the acetate as previously reported $[13,16]$ (Scheme 4; Table 2, entries 8 and 10) or by steric hindrance of the olefin partner (Table 2, entry 9).

In the case of more hindered dienic amides such as camphorsultamide 16, a good chemoselectivity was

observed as the desired cross-metathesis products of type A were isolated in moderate to good yields with no trace of mono-olefin of type B (Table 2, entries 11-14). Indeed, when a reaction mixture consisting of camphorsultamide 16, oct-1-ene ( 5 equiv.), and catalyst [ Ru$]$-III ( $10 \mathrm{~mol} \%$ ) was stirred in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at rt for 24 h , the cross-metathesis product 24 was isolated in $61 \%$ yield with a $10 / 1(E, E)$ $\mathbf{2 4} /(E, Z) \mathbf{- 2 4}$ ratio (Table 2 , entry 11 ). When the 1 -acet-oxy-but-3-ene and the ( $Z$ )-1,4-diacetoxybut-2-ene were involved in the CM reaction with camphorsultamide 16,
dienic amides 25 and 26 were isolated in similar yields $(40 \%)$ with a $(E, E) /(E, Z)$ ratio of $9 / 1$ and $5 / 1$, respectively (Table 2, entries 12 and 13). Finally, when the ( $Z$ )-1,4-dichlorobut-2-ene was utilized in the CM with 16, diene 27 was isolated in $57 \%$ yield with an $(E, E)-\mathbf{2 7} /(E, Z)-27$ ratio of $16 / 1$ (Table 2, entry 14 ).

## 4. Conclusion

Cross-metathesis reactions between dienic amides and a variety of olefins turned out to be highly chemoselective at the $\gamma, \delta$-double bond producing mostly the corresponding dienes of type $\mathbf{A}$. When a mixture of diene of type $\mathbf{A}$ and mono-olefin of type $\mathbf{B}$ is obtained, a decrease in the amount of catalyst and/or the reaction time can result in higher chemoselectivity in favor of $\mathbf{A}$. This method allows
the formation of functionalized dienic amides under mild conditions. As the Weinreb amides $\mathbf{1 8 - 2 3}$ can be transformed into aldehydes, ketones or carboxylic acids and as the optically active amides $\mathbf{2 4 - 2 7}$ can be involved in diastereoselective reactions, the CM reaction of dienic amides provides a valuable alternative for the preparation of useful intermediates.

### 5.1. General comments

Flash chromatography was performed with Merck Geduran Si60 silica gel (40-63 UM). Infrared (IR) spectra were recorded on a Bruker TENSOR ${ }^{\text {TM }} 27$ (IRFT), wavenumbers are indicated in $\mathrm{cm}^{-1} .{ }^{1} \mathrm{H}$ NMR spectra were recorded on a Bruker AVANCE 400 at 400 MHz and data are reported as follows: chemical shift in ppm from tetramethylsilane as an internal standard, multiplicity ( $\mathrm{s}=$ singlet, $\mathrm{d}=$ doublet, $\mathrm{t}=$ triplet, $\mathrm{q}=$ quartet, $\mathrm{m}=$ multiplet or overlap of non-equivalent resonances), integration. ${ }^{13} \mathrm{C}$ NMR spectra were recorded on a Bruker AVANCE 400 at 100 MHz and data are reported as follows: chemical shift in ppm from tetramethylsilane with the solvent as an internal indicator $\left(\mathrm{CDCl}_{3} \delta: 77.0 \mathrm{ppm}\right)$. Mass spectra with electronic impact (MS-EI) were recorded from a Hew-lett-Packard tandem 5890 A GC ( 12 m capillary column) $5971 \mathrm{MS}(70 \mathrm{eV})$. High resolution mass spectra (HRMS) were performed by the Centre de Spectrochimie de l'Ecole Normale Supérieure Ulm (Paris).

### 5.2. General procedure for CM reactions between methyl sorbate and olefin cross-partners

To a solution of methyl sorbate $(150 \mathrm{mg}, 1.2 \mathrm{mmol}$, 1 equiv.) and olefin partner ( 6 mmol , 5 equiv.) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( $c=0.1-0.2 \mathrm{M}$ ) was added the Grubbs-Hoveyda catalyst [Ru]-III ( $18.5 \mathrm{mg}, 0.030 \mathrm{mmol}, 0.025$ equiv.). After 24 h stirring, another portion of Grubbs-Hoveyda catalyst [Ru]-III was added ( 0.025 equiv.). After 24 h , silica was added to the reaction mixture and after evaporation of the solvent, the pad of silica was loaded on top of a silica gel column and a flash chromatography purification was achieved.

### 5.3. General procedure for CM reactions with dienic amides

To a solution of sorbamide ( $1 \mathrm{mmol}, 1$ equiv.) and the olefin partner ( $5 \mathrm{mmol}, 5$ equiv.) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(c=0.1-$ 0.2 M ) was added Grubbs-Hoveyda catalyst [Ru]-III ( $64 \mathrm{mg}, 0.10 \mathrm{mmol}, 0.1$ equiv.). The solution was stirred for 24 h and silica was then added to the reaction mixture. After evaporation of the solvent, the pad of silica was loaded on top of a silica gel column and a flash chromatography purification was achieved.

### 5.3.1. (2E,4E)-N,N-Diisopropylundeca-2,4-dienamide (17)

Purification on silica gel (AcOEt/Petroleum Ether: 15/85 to $20 / 80$ ) afforded 17 in $36 \%$ yield as a mixture of the dienes $(E, E)-17 /(E, Z)-17(28 / 1)$.
