

# Ni-Zr (Nickel-Zirconium)

H. Okamoto

Ni-Zr samples containing 41.2-43.0 at.% Zr were annealed at 700, 800, and 1000 °C and furnace cooled to examine the homogeneity range of  $\text{Ni}_{10}\text{Zr}_7$  by means of x-ray diffraction and metallographic studies [2004Tak]. The result indicated that the homogeneity range of  $\text{Ni}_{10}\text{Zr}_7$  is very narrow. Figure 1 shows the Ni-Zr phase diagram assessed by [1991Nas] with the  $\text{Ni}_{10}\text{Zr}_7$  phase field as modified by [2004Tak]. In the original diagram, the width of the  $\text{Ni}_{10}\text{Zr}_7$  phase was approximately 2.5 at.%. This result is consistent with the criterion given by [1993Oka] that a two-phase field becoming increasingly wider at higher temperatures is unlikely. In this regard,  $\text{Ni}_5\text{Zr}$  and  $\text{Ni}_3\text{Zr}$  may also have a narrow homogeneity range.
