#### Summary

The chlorine-atom initiated and Hg  $6({}^{3}P_{1})$ -photosensitized oxidation of CH<sub>2</sub>CCl<sub>2</sub> was studied at 32 °C. In both cases a long chain process was involved in which the major product was CH<sub>2</sub>ClCCl(O), and the minor product was CCl<sub>2</sub>O. In the chlorine-atom initiated study, CO was not an initial product, but appeared as a minor secondary product suggesting CHClO as a precursor. In the Hg-photosensitized study, minor amounts of CO appear to be an initial product.

The chain steps in both studies are:

$Cl + CH_2CCl_2$	$\rightarrow$ CH <sub>2</sub> ClCCl <sub>2</sub>
$CH_2ClCCl_2 + O_2$	$\rightarrow$ CH <sub>2</sub> CCl <sub>2</sub> O <sub>2</sub>
$2 CH_2 ClCCl_2 O_2$	$\rightarrow$ 2CH <sub>2</sub> ClCCl <sub>2</sub> O + O <sub>2</sub>
CH <sub>2</sub> ClCCl <sub>2</sub> O	$\rightarrow$ CH <sub>2</sub> ClCCl(O) + Cl

In the chlorine-atom initiated oxidation  $-\Phi\{CH_2CCl_2\} = \Phi\{CH_2ClCCl(O)\} =$ 172 independent of  $[CH_2CCl_2]$ ,  $[O_2]$ , or  $I_a$ . In the Hg-photosensitized oxidation, both  $-\Phi\{CH_2CCl_2\}$  and  $\Phi\{CH_2ClCCl(O)\}$  were proportional to  $[CH_2CCl_2]$ , but independent of  $I_a$  and  $[O_2]$  (for  $[O_2]/[CH_2CCl_2] < 1.8$ ). Thus the termination steps are different in the two systems, and various possibilities are discussed.

## Introduction

The free-radical oxidation of  $CH_2CCl_2$  apparently has not been studied previously. However, for  $C_2Cl_4$  both chlorine-atom initiated [1 - 5] and Hg photosensitized [6] oxidation have been studied. Likewise for  $C_2HCl_3$  the chlorine-atom initiated [7, 8] and Hg photosensitized [9] oxidation have been studied. The results for  $C_2Cl_4$  and  $C_2HCl_3$  were analogous. The oxidation was a long free-radical chain process, and for  $C_2HCl_3$ , the chain steps are:

\*Fulbright Fellow.

$Cl + C_2HCl_3$	$\rightarrow$ R	(1)
$R + O_2$	$\rightarrow \mathrm{RO}_2$	(2)
2RO <sub>2</sub>	$\rightarrow$ 2RO + O <sub>2</sub>	( <b>3</b> a)
RO	$\rightarrow$ CHCl <sub>2</sub> CCl(O) + Cl	(4a)
	$\rightarrow$ CO + HCl + CCl <sub>3</sub>	(4b)
$CCl_3 + \frac{1}{2}O_2$	$\rightarrow$ CCl <sub>2</sub> O + Cl	(5)

where R is either  $CHCl_2CCl_2$  or  $CCl_3CHCl$ . Reaction (4a) occurs when RO is  $CHCl_2CCl_2O$ , and reaction (4b) occurs when RO is  $CCl_3CHClO$ .

The rate laws were different for chlorine-atom initiation and Hg photosensitization. For chlorine atom initiation, the chain length was independent of all reaction parameters (at least for sufficiently high  $O_2$  pressures). Initiation and termination were, respectively:

$$Cl_2 + h\nu \rightarrow 2Cl$$
 (6)

$$2\mathrm{RO}_2 \quad \rightarrow \ (\mathrm{RO})_2 + \mathrm{O}_2 \tag{3b}$$

With Hg-sensitization, the chain length was proportional to the olefin pressure. The initiation steps proposed were:

$Hg^{\star} + C_2HCl_3$	$\rightarrow \text{HgCl} + \text{C}_2\text{HCl}_2$	(7)
C HC + O		(8)

$$U_2HU_2 + U_2 \longrightarrow U_2HU_2U_2 \tag{6}$$

$$C_2HCl_2O_2 + C_2HCl_3 \rightarrow R' + \text{products}$$
 (9)

where R' is either  $C_2H_2Cl_3$  or  $C_2HCl_4$ . The termination would then be first order in  $C_2HCl_2O_2$ :

$$C_2HCl_2O_2 \rightarrow termination$$
 (10)

The mechanistic details of reaction (10) are not clear. It is needed to explain the rate law, and possibly occurs on the wall of the reaction vessel.

As part of a continuing study on chloro-olefin oxidation, we have extended our studies to  $CH_2CCl_2$ . The results of the free-radical oxidation of that molecule are presented here.

# Experimental

The experimental procedure has been described elsewhere [5, 6, 10]. The T-shaped reaction vessel was situated in the sample beam of a Beckman IR-10 spectrometer for continual analysis of  $CH_2CCl_2$  removal and  $CH_2ClCCl(O)$  formation by their respective bands at 1640 and 1850 cm<sup>-1</sup>.  $CCl_2O$  was analyzed after the radiation was discontinued, because its infrared bands were masked by the other species present. The  $CCl_2O$  was isolated for the analysis in the fraction volatile at -90 °C but condensable at -196 °C. CO analysis was by gas chromatography after the irradiation was terminated.

#### Results

In both the chlorine-atom initiated and Hg-photosensitized oxidation a long chain process is involved. The major product is  $CH_2ClCCl(O)$ , and its quantum yield of formation,  $\Phi\{CH_2ClCCl(O)\}$ , is essentially equal to the quantum yield of  $CH_2CCl_2$  consumption,  $-\Phi\{CH_2CCl_2\}$ . In both studies minor amounts of  $CCl_2O$  and CO are also found. There was no evidence for  $CH_2O$ ,  $CHCl_2CH(O)$ , HCl or CHClO production. For CHClO the upper limit for its quantum yield is 1.0 in the chlorine-atom initiated oxidation.

The quantum yields for several runs in the chlorine-atom initiated oxidation are shown in Table 1.  $-\Phi\{CH_2CCl_2\} = \Phi\{CH_2ClCCl(O)\} = 172$ independent of a change in  $[CH_2CCl_2]$  by a factor of 5.6,  $[O_2]$  by a factor of 100, or the absorbed intensity,  $I_a$ , by a factor of 7.5. The values for  $\Phi\{CCl_2O\}$  show considerable scatter but are about 2. Initial quantum yields of CO are immeasurable ( $\Phi\{CO\} < 0.2$ ), but in one run which was allowed to stand for 1 h after irradiation before analysis,  $\Phi\{CO\} \sim 1$ .

The reaction proceeds proportionately with irradiation time, as can be seen from Figs. 1 and 2 which are plots, respectively, of the intensitynormalized  $CH_2CCl_2$  consumption and  $CH_2ClCCl(O)$  production vs. irradiation time. Both plots are linear, and all the runs can be represented by the same straight line which gives a slope (*i.e.* quantum yield) of 172 in both plots. Possibly the two runs at highest  $O_2$  pressure show some fall-off at long conversions, but this is minor, if indeed it is real.

The results for the Hg-photosensitized oxidation of  $CH_2CCl_2$  are shown in Table 2. For these experiments,  $[CH_2CCl_2]$  was varied by a factor of 13,  $[O_2]$  by a factor of 44, and  $I_a$  by a factor of 12.5. During the runs, the radiation was periodically interrupted and the cell shaken to eliminate the inhibition that occurs if shaking is not done. Here the quantum yields of the chlorinated compounds are much smaller than for the chlorine-atom initiated oxidation. Also  $-\Phi\{CH_2CCl_2\}$  and  $\Phi\{CH_2ClCCl(O)\}$  increase with  $[CH_2CCl_2]$ , but  $\Phi\{CO\}$  and  $\Phi\{CCl_2O\}$  are independent of parameters and are each between 0.5 and 1.0.

Figure 3 shows log-log plots of  $-\Phi\{CH_2CCl_2\}$  and  $\Phi\{CH_2ClCCl(O)\}$ vs.  $[CH_2CCl_2]$ . The plots can be fitted by lines of slope 1.0 indicating that the quantum yields are proportional to the  $CH_2CCl_2$  pressure. The two runs at highest  $[O_2]/[CH_2CCl_2]$  ratio lie noticeably below the line that best fits the other points, suggesting that  $O_2$  has an inhibiting effect.

## Discussion

The main chain sequence certainly must be:

Fig. 3. Plot of  $-\Phi{CH_2CCl_2}$  ( $\bigcirc$ ,  $\bullet$ ) or  $\Phi{CH_2ClCCl(O)}$  ( $\triangle$ ,  $\blacklozenge$ ) vs.  $[CH_2CCl_2]$  in the Hgphotosensitized oxidation of  $CH_2CCl_2$  at 32 °C. The plot for  $-\Phi{CH_2CCl_2}$  has been raised by a factor of 10 for clarity.  $\triangle$ ,  $\bigcirc$ ,  $[O_2]/[CH_2CCl_2] < 1.8$ ;  $\bullet$ ,  $\blacktriangle$ ,  $[O_2]/[CH_2CCl_2] > 1.8$ .

For every  $CH_2CCl_2$  consumed one molecule of  $CH_2ClCCl(O)$  is produced. A possible minor route which might compete with reaction (11a) is:

$$Cl + CH_2CCl_2 \rightarrow CCl_3CH_2$$
 (11b)

The CCl<sub>3</sub>CH<sub>2</sub> radical would oxidize as follows:

$$CCl_{3}CH_{2} + (\frac{1}{2})O_{2} \rightarrow CCl_{3}CH_{2}O \rightarrow CH_{2}O + CCl_{3}$$
$$CCl_{3} + (\frac{1}{2})O_{2} \rightarrow CCl_{2}O + Cl$$

The upper limit to  $k_{11b}/k_{11a} = \Phi\{\text{CCl}_2\text{O}\}/\Phi\{\text{CH}_2\text{ClCCl}(\text{O})\} \sim 0.01$ . We found no CH<sub>2</sub>O, but we could have missed the small amount produced.

In the chlorine-atom sensitized oxidation, the initiation occurs via reaction (6). Since the quantum yields are insensitive to the reaction parameters, there are only two possible terminating reactions:

$$2CH_2ClCCl_2O_2 \rightarrow (CH_2ClCCl_2O)_2 + O_2$$
(13b)

$$CH_2ClCCl_2O \rightarrow CH_2Cl + CCl_2O$$
 (14b)

In a separate study [11], we have shown that  $CH_2Cl$  always oxidizes to CHClO in a non-chain process. Thus both reaction (13b) and (14b) are terminating steps.

If reaction (13b) is the sole terminating step then  $k_{13a}/k_{13b} = 86$ . Furthermore if  $(CH_2ClCCl_2O)_2$  does not decompose, then  $k_{11b}/k_{11} \sim 0.01$ . However, if  $(CH_2ClCCl_2O)_2$  decomposes, presumably to give  $CCl_2O$  and CHClO, then reaction (11b) must be even less important, because  $CCl_2O$  is produced *via* termination.

On the other hand, if reaction (14b) is the sole termination step then  $k_{14a}/k_{14b} = 86$  and reaction (11b) does not occur at all, because all the CCl<sub>2</sub>O comes from the termination ( $\Phi$ {CCl<sub>2</sub>O} = 2.0). Of course, if reaction (11b) does not occur at all, then  $\Phi$ {CCl<sub>2</sub>O} should equal  $\Phi$ {CHClO} by either termination mechanism. Our results indicate that  $\Phi$ {CCl<sub>2</sub>O} ~ 2 and  $\Phi$ {CHClO}  $\leq 1$ . (Presumably  $\Phi$ {CHClO}  $\sim 1$ , since for the run that was allowed to stand before CO analysis,  $\Phi$ {CO}  $\sim 1$ . The CO comes from the thermal decomposition of CHClO [12].) Thus our very tentative conclusion is that reaction (11b) occurs to some extent, and that termination leads to (CH<sub>2</sub>ClCCl<sub>2</sub>O)<sub>2</sub> part, but not all, of the time.

In the Hg-photosensitized oxidation the initiation and termination possibilities are more numerous. The possibility that Hg-photosensitization gives exclusively molecular elimination of HCl can be discarded, since then there would be no chain process. We can also discard the possibility that the double bond is ruptured to produce  $CH_2$  and  $CCl_2$ . Initiation by  $CCl_2$ radicals does give the same products, but the rate law is intensity-dependent [10], contrary to our observations here ( $CH_2$  reacts with  $O_2$  to give HCOOH or  $H_2O + CO$ , so it would play no role).

Thus, as in the case with  $C_2Cl_4$  and  $C_2HCl_3$ , Hg-photosensitization leads to the formation of free radicals. There are two possible radicals to consider,  $CH_2CCl$  or  $CCl_2CH$ . They could be produced by several routes, but the kinetics are indistinguishable. Among the possibilities are:

 $Hg^{*} + CH_{2}CCl_{2} \rightarrow HgCl + CH_{2}CCl$  $\rightarrow Hg + H + CCl_{2}CH$ 

or

 $\begin{array}{rcl} \mathrm{Hg}^{\star} + \mathrm{CH}_{2}\mathrm{CCl}_{2} & \rightarrow & \mathrm{Hg} + \mathrm{CH}_{2}\mathrm{CCl}_{2}^{\star} \\ \mathrm{CH}_{2}\mathrm{CCl}_{2}^{\star} + \mathrm{Hg} & \rightarrow & \mathrm{HgCl} + \mathrm{CH}_{2}\mathrm{CCl} \\ \mathrm{CH}_{2}\mathrm{CCl}_{2}^{\star}(+ \mathrm{Hg}) & \rightarrow & \mathrm{H} + \mathrm{CCl}_{2}\mathrm{CH}(+ \mathrm{Hg}) \end{array}$ 

or

 $Hg^{\star} + O_{2} \rightarrow Hg + O_{2}^{\star}$   $O_{2}^{\star} + CH_{2}CCl_{2} \rightarrow CH_{2}CCl_{2}^{\star} + O_{2}$   $CH_{2}CCl_{2}^{\star} + Hg \rightarrow HgCl + CH_{2}CCl$   $CH_{2}CCl_{2}^{\star}(+ Hg) \rightarrow H + CCl_{2}CH (+ Hg)$ 

In any event either  $CH_2CCl$  or  $CCl_2CH$  must be produced. In order to give the observed rate law, *i.e.*  $\Phi\{CH_2ClCCl(O)\}$  being proportional to  $[CH_2CCl_2]$ , these radicals, designated R<sup>"</sup>, must obey the following kinetics:

$$\mathbf{R}'' + \mathbf{O_2} \qquad \rightarrow \mathbf{R}''\mathbf{O_2} \tag{15}$$

$$R''O_2 \rightarrow \text{termination}$$
(16)  
$$R''O_2 + CH_2CCl_2 \rightarrow CH_3CCl_2 + \text{stable products}$$
(17a)

$$\rightarrow CH_2ClCCl_2 + stable products$$
(17b)

Reaction (16) probably occurs on the wall and is the dominant reaction for  $R''O_2$ . Reaction (17) is the chain-initiating step and occurs 4 - 40% of the time (the chain lengths in the Hg-photooxidation are 4 - 40% of those in the chlorine-atom initiated oxidation). Thus the stable products of reaction (17), whatever they might be (glyoxals, HCl, CO), are unimportant.

Reaction (16), on the other hand, must account for some of the  $CCl_2O$  and CO produced, since the sum of their quantum yields exceeds 1.0. It is not at all clear how reaction (16) proceeds, since ultimately it must involve another free radical to lead to stable products. However, speculative possibilities are:

 $CH_2CClO_2 \rightarrow HCl + HCO + CO$  $CCl_2CHO_2 \rightarrow CCl_2O + HCO$ 

where HCO terminates via:

 $HCO + O_2 \rightarrow CO + HO_2 \rightarrow (\frac{1}{2})H_2O_2 + (\frac{1}{2})O_2$ 

It is interesting to note that  $CH_2CClO_2$  does not give  $CCl_2O$ . Since  $\Phi\{CCl_2O\}$  is independent of  $[CH_2CCl_2]$ , it must come mainly from termination, and  $CCl_2CHO_2$  would be the more important  $R''O_2$  radical.

Finally we point out that at high values of  $[O_2]/[CH_2CCl_2]$ , the quantum yields in the Hg-photosensitization are reduced because of the reactions:

 $Hg^{\star} + O_2 \rightarrow Hg + O_2^{\star}$  $O_2^{\star} + O_2 \rightarrow 2O_2 \text{ (or O + O_3)}$
