Received: February 4, 1997; In Final Form: April 1, 1997<sup>⊗</sup>

The hydrogen-bonded complexes between C<sub>2</sub>H<sub>4</sub> and HNO<sub>3</sub>, and their deuterated analogs, have been isolated and characterized in argon matrices. The concentration studies, matrix annealing, and UV irradiation effects prove formation of stable 1/1  $\pi$ -electron hydrogen-bonded complexes isolated in two trapping sites. Eight perturbed HNO<sub>3</sub> vibrations and three perturbed C<sub>2</sub>H<sub>4</sub> vibrations were identified for this complex. The spectra also indicate the existence of a less stable 1/1  $\pi$ -electron hydrogen-bonded complex for which one perturbed frequency due to the OH stretching mode was identified. Photochemistry of the complexes was also studied with the 266 nm laser line and with a medium-pressure mercury lamp. The photolysis products of HNO<sub>3</sub>, OH and NO<sub>2</sub> radicals, recombine in the matrix cage to form nitric acid, and peroxyxynitrous acid which are the main reaction products. The new major product of photolysis of the C<sub>2</sub>H<sub>4</sub>–HNO<sub>3</sub> complex is ethylene glycol nitrite formed in double-addition reaction of OH and NO<sub>2</sub> radicals to the C=C bond of the ethylene molecule.

## 1. Introduction

Nitric acid, formed via the reaction of OH with NO<sub>2</sub>, is an important species in the atmosphere. In the stratosphere, it is a temporary reservoir of odd nitrogen and a constituent of polar stratospheric clouds. In urban air it is a major component of photochemical smog,<sup>1,2</sup> and it contributes to acid deposition and to nitrate-containing aerosol formation. Due to its importance, during the past decade, considerable attention has been directed toward its reaction with OH radical<sup>3</sup> and its photodissociation in the gas phase<sup>4–6</sup> and in matrices.<sup>7,8</sup> Nitric acid is a strong proton donor, and the knowledge of the photochemistry of molecular complexes formed between HNO<sub>3</sub> and other atmospheric species is of great interest for understanding the chemistry that occurs in the polluted troposphere. However there is very little information in this area. Thirty years ago the complexes of nitric acid with a series of ethers in the gas phase were reported.<sup>9,10</sup> Recently Barnes studied nitric acid complexes with N<sub>2</sub>, CO, H<sub>2</sub>O, and NH<sub>3</sub> by means of infrared spectroscopy and matrix isolation techniques.<sup>11</sup> The infrared spectra of the complexes between nitric acid and ethylene have not been studied so far.

Ethylene and propylene are the main alkenes observed in the troposphere near large urban sources of hydrocarbon emission. It is well-known that ethylene is a  $\pi$ -electron donor and some work was focused on the hydrogen bond formed between ethylene and hydrogen halides<sup>12,13</sup> or water.<sup>14</sup>

As an extension of our previous study on the nitric acid–methane complex,<sup>15</sup> this paper presents the results of matrix isolation studies of the nitric acid–ethylene system. Infrared spectroscopic studies of the UV photolysis of the complex are also reported.

## 2. Experimental Section

Nitric acid was prepared by adding drop by drop concentrated (98%) sulfuric acid (or deuterated sulfuric acid) to solid

potassium nitrate. In order to minimize the HNO<sub>3</sub> decomposition, the reaction vessel was kept at a temperature of 0 °C. The reaction product was vacuum distilled. The mixtures of C<sub>2</sub>H<sub>4</sub>–(C<sub>2</sub>D<sub>4</sub>)/Ar and HNO<sub>3</sub>(DNO<sub>3</sub>)/Ar were prepared using standard manometric techniques. The two mixtures were simultaneously deposited onto a gold-plated copper mirror held at 20 K by a closed cycle helium refrigerator (Air Products, Displex 202A). The concentration of the studied matrices varied in the range 1/1/800 to 1/4/500. Infrared spectra were recorded with the matrix maintained at ca. 11 K. The spectra were registered at 0.5 cm<sup>-1</sup> resolution in a reflection mode, with a Bruker 113v Fourier transform infrared spectrometer.

Two different light sources have been employed for photolysis: a medium-pressure Hg lamp (200 W) and a Nd:YAG laser (Quantel YG 781C 20), 266 nm, 20 Hz.

## 3. Vibrational Spectra of Parent Molecules

The spectra of the reactants, nitric acid and ethylene in argon, were recorded for comparison with the spectra of nitric acid/ethylene/argon matrices.

**3.1. HNO<sub>3</sub>/Ar Samples.** The IR spectrum of HNO<sub>3</sub> in the gas phase was first reported by Cohn.<sup>16</sup> Later McGraw<sup>9</sup> analyzed the spectra of all HNO<sub>3</sub> isotopomers (H, D, <sup>14</sup>N, <sup>15</sup>N) and performed force field calculations for nitric acid molecule. More recently, a number of infrared bands (fundamentals and combinations) have been analyzed at high resolution (refs 17–19 and references therein). In particular the  $\nu_4$  mode ( $\delta_{\text{NOH}}$ ) was reassigned, and resonances between  $3\nu_9$  (1288.9 cm<sup>-1</sup>),  $\nu_4$  (1303.6 cm<sup>-1</sup>),  $\nu_3$  (1326.18 cm<sup>-1</sup>) and  $\nu_5 + \nu_9$  (1343.65 cm<sup>-1</sup>) transitions were analyzed<sup>19</sup> as well as those between  $\nu_5$  (879.1 cm<sup>-1</sup>) and  $2\nu_9$  (896.4 cm<sup>-1</sup>).<sup>18</sup>

The IR spectra of three isotopic species of nitric acid isolated in nitrogen and argon have been reported by W. J. Chen et al.<sup>8</sup> Spectra of HNO<sub>3</sub> in argon recorded in this work are in good agreement with the literature data. Bands due to OH stretching ( $\nu_1$ ) and OH torsion ( $\nu_9$ ) appeared as doublets, the splitting was

<sup>a</sup> The frequencies indicated by I <sub>$\alpha$</sub> , I <sub>$\beta$</sub> , II correspond to the 1/1 C<sub>2</sub>H<sub>4</sub>–HNO<sub>3</sub> complexes; the frequencies indicated by III, IV, and V correspond to higher order (C<sub>2</sub>H<sub>4</sub>)<sub>n</sub>HNO<sub>3</sub> complexes.

also observed for the in plane and out of plane bending modes ( $\nu_7$ ,  $\nu_8$ , respectively) as well as for the NO<sub>2</sub> stretching mode ( $\nu_2$ ).

As previously reported in the Experimental Section, it is difficult to obtain a pure HNO<sub>3</sub> sample, and weak absorptions due to NO<sub>2</sub> traces and to the NO<sub>2</sub>••HNO<sub>3</sub> complex<sup>11</sup> were observed in the studied spectra.

**3.2. Ethylene/Ar Samples.** The infrared and Raman spectra of the ethylene monomer and dimer in an argon matrix have been previously reported.<sup>20,21</sup> Some modes that are IR inactive for the ethylene monomer were observed for the dimer. Both in solid argon<sup>20,21</sup> and in solid xenon<sup>22</sup> most of the ethylene monomer fundamentals appear as doublets. Our spectra are in agreement with the previous results. The vibrational spectrum of C<sub>2</sub>D<sub>4</sub> in argon, not reported before, showed absorptions at 2344 cm<sup>-1</sup> ( $\nu_a$  CH<sub>2</sub>), 2205.4 cm<sup>-1</sup> ( $\nu_s$  CH<sub>2</sub>), 1074.7 cm<sup>-1</sup> ( $\delta$  CH<sub>2</sub>), 719.2 cm<sup>-1</sup> ( $\omega$  CH<sub>2</sub>), and 620 cm<sup>-1</sup> ( $\rho$  CH<sub>2</sub>).

#### 4. Vibrational Spectra of the Nitric Acid–Ethylene Complexes

Infrared spectra of matrices obtained by codeposition of HNO<sub>3</sub>/Ar = 1/1000, 1/500, 1/200, 1/100 samples and C<sub>2</sub>H<sub>4</sub>–(C<sub>2</sub>D<sub>4</sub>)/Ar = 1/400, 1/250, 1/100 samples have been studied. In three experiments deuterium-enriched (ca. 50%) nitric acid samples, D(H)NO<sub>3</sub>/Ar = 1/250, 1/150, were codeposited with a C<sub>2</sub>H<sub>4</sub>(C<sub>2</sub>D<sub>4</sub>)/Ar = 1/250 sample. The obtained spectra were compared with the spectra of HNO<sub>3</sub>, DNO<sub>3</sub>, C<sub>2</sub>H<sub>4</sub>, and C<sub>2</sub>D<sub>4</sub> in argon. The observed product absorptions due to the nitric acid–ethylene complexes of different isotopic composition are listed in Table 1; Figures 1–4 illustrate some spectral regions of interest.

The concentration studies and matrix annealing allowed us to identify the bands due to the 1/1 complexes between nitric acid and ethylene. The spectra of the 1/1 HNO<sub>3</sub>–C<sub>2</sub>H<sub>4</sub> complexes will be described below by considering absorptions due to the perturbed H(D)NO<sub>3</sub> and C<sub>2</sub>H<sub>4</sub>, C<sub>2</sub>D<sub>4</sub> submolecules in the complex.

**4.1. HNO<sub>3</sub>, DNO<sub>3</sub> Submolecules in the Complex.**  $\nu(\text{OH})$ ,  $\nu(\text{OD})$  Regions. When HNO<sub>3</sub> and C<sub>2</sub>H<sub>4</sub> molecules were present in an argon matrix, a strong doublet appeared in the studied spectra at 3307.4, 3300.8 cm<sup>-1</sup> (I <sub>$\alpha$</sub> , I <sub>$\beta$</sub>  respectively) and additional weaker bands were observed at 3325.1 cm<sup>-1</sup> (II) and

at 3320.3 cm<sup>-1</sup> (III). The relative intensities of the four bands were approximately constant within the range of concentrations studied. Figure 1'a,b shows the bands I <sub>$\alpha$</sub> , I <sub>$\beta$</sub> , II, and III in the spectra of the HNO<sub>3</sub>/C<sub>2</sub>H<sub>4</sub>/Ar = 1/1500 matrix after deposition (a) and after matrix irradiation for 1 h with a 266 nm YAG laser line (b); (spectrum b is scaled in such a way that the intensity of the I <sub>$\alpha$</sub>  band is the same in the spectra a and b). All product absorptions were destroyed by matrix irradiation, but the band I <sub>$\beta$</sub>  was more sensitive whereas the band II was less sensitive to irradiation than the band I <sub>$\alpha$</sub> . Figure 1'c,d demonstrates the influence of annealing on the HNO<sub>3</sub>/C<sub>2</sub>H<sub>4</sub>/Ar = 1/1/800 matrix. The intensity of the absorption I <sub>$\beta$</sub>  slightly increased with respect to the band I <sub>$\alpha$</sub>  after matrix annealing, the absorption II strongly decreased whereas the band III considerably increased, and additional weak bands occurred at 3287.7 cm<sup>-1</sup> (IV) and at 3280.7 cm<sup>-1</sup> (V).

A similar pattern of bands was observed in the  $\nu(\text{OH})$  region in the spectra of HNO<sub>3</sub>/C<sub>2</sub>D<sub>4</sub>/Ar matrices; the bands I <sub>$\alpha$</sub> , I <sub>$\beta$</sub> , II, and III were identified at 3304.7, 3297.8, 3321.6, and 3316.7 cm<sup>-1</sup>; the absorptions IV and V occurred after matrix annealing at 3284.3, 3277.2 cm<sup>-1</sup>. In the spectra of Ar/D(H)NO<sub>3</sub>/C<sub>2</sub>H<sub>4</sub> matrices containing deuterium-enriched nitric acid the deuterium counterparts of the bands I <sub>$\alpha$</sub> , I <sub>$\beta$</sub> , II, and III were identified in the  $\nu(\text{OD})$  region at 2456.2, 2451.6, 2468.5, and 2464.9 cm<sup>-1</sup>, whereas in the spectra of Ar/D(H)NO<sub>3</sub>/C<sub>2</sub>D<sub>4</sub> matrices the corresponding I <sub>$\alpha$</sub> , I <sub>$\beta$</sub> , II, and III bands appeared, respectively, at 2454.3, 2449.5, 2466.2, and 2462.5 cm<sup>-1</sup>. In Figure 1'' the  $\nu(\text{OD})$  regions in the spectra of the D(H)NO<sub>3</sub>/C<sub>2</sub>H<sub>4</sub>/Ar = 1/1/500 and D(H)NO<sub>3</sub>/C<sub>2</sub>D<sub>4</sub>/Ar = 1/1/500 matrices are presented.

The concentration and annealing studies demonstrate that the bands I <sub>$\alpha$</sub> , I <sub>$\beta$</sub> , and II correspond to the 1/1 C<sub>2</sub>H<sub>4</sub>••HNO<sub>3</sub> complexes characterized by the  $\nu(\text{OH})$  stretching vibration, respectively, at 3307.4, 3300.8, and 3325.1 cm<sup>-1</sup>. The concentration of the complexes characterized by the I <sub>$\alpha$</sub>  and I <sub>$\beta$</sub>  bands is much higher than the concentration of the complex II, as indicated by much larger intensity of the 3307.4, 3300.8 cm<sup>-1</sup> bands as compared to the 3325.1 cm<sup>-1</sup> band. The bands due to the complexes I <sub>$\alpha$</sub>  and I <sub>$\beta$</sub>  were identified in all regions of HNO<sub>3</sub> fundamentals and in the regions of the  $\nu_7$ ,  $\nu_{12}$  vibrations of C<sub>2</sub>H<sub>4</sub> molecule.

The absorption III occurs in all studied spectra as a weak band after matrix deposition and increases strongly after matrix

**Figure 1.** (1')  $\nu(\text{OH})$  region in the spectra of  $\text{HNO}_3/\text{C}_2\text{H}_4/\text{Ar}$  matrices. The spectra of the  $\text{HNO}_3/\text{C}_2\text{H}_4/\text{Ar} = 1/1/500$  matrix after deposition (a) and after irradiation for 100 min with 266 nm YAG laser line (b); spectrum b is scaled by 6. The spectra of the  $\text{HNO}_3/\text{C}_2\text{H}_4/\text{Ar} = 1/1/800$  matrix after deposition (c) and after matrix annealing to 33 K for 10 min (d). (1'')  $\nu(\text{OD})$  region in the spectra of  $\text{D}(\text{H})\text{NO}_3/\text{C}_2\text{H}_4(\text{D}_4)/\text{Ar}$ . The spectra of the  $\text{D}(\text{H})\text{NO}_3/\text{C}_2\text{H}_4/\text{Ar} = 1/1/500$  matrix after deposition (a) and after matrix irradiation for 120 min with a medium-pressure mercury lamp (b); spectrum b is scaled by 5. The spectra of the  $\text{D}(\text{H})\text{NO}_3/\text{C}_2\text{H}_4/\text{Ar} = 1/1/500$  matrix after deposition (c) and after matrix annealing to 33 K for 10 min (d).

**Figure 2.** 1710–1650  $\text{cm}^{-1}$  (2') and 1330–1300  $\text{cm}^{-1}$  (2'') regions in the spectra of  $\text{HNO}_3/\text{C}_2\text{H}_4/\text{Ar} = 1/1/500$  (a),  $\text{D}(\text{H})\text{NO}_3/\text{C}_2\text{H}_4/\text{Ar} = 1/1/500$  (b), and  $\text{D}(\text{H})\text{NO}_3/\text{Ar} = 1/500$  (c) matrices.

annealing; the bands IV and V are observed only after matrix annealing. The bands III, IV, and V are tentatively assigned to higher order  $\text{HNO}_3(\text{C}_2\text{H}_4)_n$  complexes.

**1700–1250  $\text{cm}^{-1}$  Region.** Three fundamentals of the nitric acid monomer appear in the 1700–1250  $\text{cm}^{-1}$  region:  $\nu_2$ ,  $\text{NO}_2$  asymmetric stretch (1699.4, 1696.2  $\text{cm}^{-1}$ ),  $\nu_3$ ,  $\text{NOH}$  in plane bend, and  $\nu_4$ ,  $\text{NO}_2$  symmetric stretch (1304.4  $\text{cm}^{-1}$  and 1321.4, 1318.7  $\text{cm}^{-1}$ , respectively, according to ref 18). In the spectra of  $\text{HNO}_3/\text{C}_2\text{H}_4/\text{Ar}$  matrices the product absorptions were identified in this region at 1688.8, 1686.2, 1400.8, 1394.4,  $\text{cm}^{-1}$  and at 1307.6  $\text{cm}^{-1}$ . The annealing and irradiation experiments

demonstrate that the 1688.8, 1394.4  $\text{cm}^{-1}$  absorptions correspond to the complex  $\text{I}_\alpha$ , whereas the 1686.2, 1400.8  $\text{cm}^{-1}$  bands correspond to the complex  $\text{I}_\beta$ . The 1688.8, 1394.4  $\text{cm}^{-1}$  and the 1686.2, 1400.8  $\text{cm}^{-1}$  bands are assigned to the perturbed  $\nu_2$ ,  $\text{NO}_2$  asymmetric stretching and  $\nu_3$ ,  $\text{NOH}$  in plane bending vibrations in  $\text{I}_\alpha$  and  $\text{I}_\beta$  complexes, respectively. The 1307.6  $\text{cm}^{-1}$  band is assigned to the perturbed  $\nu_4$ ,  $\text{NO}_2$  symmetric stretching vibration in  $\text{I}_\alpha$ ,  $\text{I}_\beta$  complexes.

In the spectra of matrices containing deuterium-enriched nitric acid,  $\text{D}(\text{H})\text{NO}_3/\text{C}_2\text{H}_4/\text{Ar}$ , the perturbed  $\nu_2$ ,  $\nu_3$  nitric acid fundamentals were shifted to 1661.7, 1036.2  $\text{cm}^{-1}$  and to 1659.4,

**Figure 3.** 910–885  $\text{cm}^{-1}$  ( $3'$ ) and 780–760  $\text{cm}^{-1}$  ( $3''$ ) regions in the spectra of  $\text{HNO}_3/\text{C}_2\text{H}_4/\text{Ar} = 1/1/500$  (a) and  $\text{D(H)NO}_3/\text{C}_2\text{H}_4/\text{Ar} = 1/1/500$  (b) matrices.

**Figure 4.** ( $4'$ ) 625–580  $\text{cm}^{-1}$  region in the spectra of  $\text{HNO}_3/\text{C}_2\text{H}_4/\text{Ar} = 1/1/500$  (a) and  $\text{HNO}_3/\text{C}_2\text{D}_4/\text{Ar} = 1/1/500$  (b) matrices. ( $4''$ ) 1080–1030  $\text{cm}^{-1}$  region in the spectra of  $\text{D(H)NO}_3/\text{Ar} = 1/500$  (a),  $\text{D(H)NO}_3/\text{C}_2\text{H}_4/\text{Ar} = 1/1/500$  (b),  $\text{D(H)NO}_3/\text{C}_2\text{D}_4/\text{Ar} = 1/1/500$  (c), and  $\text{C}_2\text{D}_4/\text{Ar} = 1/500$  matrices (d).

1041.0  $\text{cm}^{-1}$  in  $I_\alpha$  and  $I_\beta$  complexes, respectively. The corresponding  $\nu_4$  mode is observed at 1307.3  $\text{cm}^{-1}$  for both  $I_\alpha$  and  $I_\beta$  complexes. Substitution of  $\text{C}_2\text{H}_4$  with  $\text{C}_2\text{D}_4$  only slightly affected the frequencies of the observed product absorptions; the observed shifts are less than 0.3  $\text{cm}^{-1}$  (see Table 1).

**900–700  $\text{cm}^{-1}$  Region.** In the spectra of  $\text{HNO}_3/\text{C}_2\text{H}_4/\text{Ar}$  matrices the product absorptions were observed in this region at 903.5, 904.7  $\text{cm}^{-1}$  and at 768.6, 769.5  $\text{cm}^{-1}$ , respectively, in the vicinity of the  $\nu_5$ , O–NO<sub>2</sub> stretching and  $\nu_8$ , ONO<sub>2</sub> in plane bending fundamentals of the  $\text{HNO}_3$  monomer (see Figure 3). The annealing and irradiation experiments allowed us to assign the 903.5, 768.6  $\text{cm}^{-1}$  bands to the complex  $I_\alpha$  and the 904.7, 769.5  $\text{cm}^{-1}$  bands to the complex  $I_\beta$ . The product bands

observed in this region show small shift when  $\text{DNO}_3$  is substituted for  $\text{HNO}_3$  or  $\text{C}_2\text{D}_4$  is substituted for  $\text{C}_2\text{H}_4$ , as reported in Table 1.

**700–400  $\text{cm}^{-1}$  Region.** When  $\text{HNO}_3$  and  $\text{C}_2\text{H}_4$  were present in the matrix samples, the infrared spectra showed a doublet at 610.6, 608.3  $\text{cm}^{-1}$  and a sharp band centered at 600.3  $\text{cm}^{-1}$  (see Figure 4'). In the spectra of matrices containing  $\text{HNO}_3$  and  $\text{C}_2\text{D}_4$  the doublet was slightly blue shifted to 611.6, 609.4  $\text{cm}^{-1}$ . No additional absorptions were observed in this region in the spectra of  $\text{D(H)NO}_3/\text{C}_2\text{H}_4$  and  $\text{D(H)NO}_3/\text{C}_2\text{D}_4$  matrices. Assignment of the observed product bands is not straightforward. In this region are expected to appear the  $\nu_7$ , ONO<sub>2</sub> in plane bending mode and the  $\nu_9$ , OH torsion mode of the  $\text{HNO}_3$

submolecule. The observed doublet at 608.3, 610.6  $\text{cm}^{-1}$  is assigned to OH torsion in  $I_\alpha$ ,  $I_\beta$  complexes, respectively, and the absorption at 600.3  $\text{cm}^{-1}$  to the  $\nu_7$ , ONO<sub>2</sub> in plane bending mode of nitric acid in  $I_\alpha$ ,  $I_\beta$  complexes. The OH torsion mode is expected to be more sensitive to the complex type and to the complex environment than the  $\nu_7$ , ONO<sub>2</sub> in plane bending mode.

**4.2. Ethylene Submolecule in the Complex.** Three product absorptions were observed in the studied spectra in the vicinity of ethylene vibrations. They include weak absorptions at 1929.0 and 1442.4  $\text{cm}^{-1}$  assigned, respectively, to the perturbed  $\nu_7+\nu_8$  combination vibration and to the  $\nu_{12}$  vibration of the C<sub>2</sub>H<sub>4</sub> submolecule, and a medium intensity doublet at 971.7, 972.7  $\text{cm}^{-1}$  due to the perturbed  $\nu_7$  vibration of C<sub>2</sub>H<sub>4</sub> in the complex. The concentration and annealing studies demonstrate that the 971.7, 972.7  $\text{cm}^{-1}$  components of the doublet correspond to the  $I_\alpha$ ,  $I_\beta$  complexes, respectively. The frequencies of the perturbed ethylene vibrations are not sensitive to DNO<sub>3</sub> substitution, whereas in the C<sub>2</sub>D<sub>4</sub>-substituted complexes the 1929.0, 1442.4, 972.7, 971.7  $\text{cm}^{-1}$  bands are shifted, respectively, to 1514.4, 1075.8 and 743.1, 740.0  $\text{cm}^{-1}$ . Figure 4'' presents the region of the  $\nu_{12}$ , C<sub>2</sub>D<sub>4</sub> mode in the HNO<sub>3</sub>/C<sub>2</sub>D<sub>4</sub>/Ar = 1/1/500 matrix.

### 5. Bonding of the Nitric Acid–Ethylene Complex

Eight perturbed HNO<sub>3</sub> vibrations and two perturbed C<sub>2</sub>H<sub>4</sub> vibrations were identified for the C<sub>2</sub>H<sub>4</sub>⋯HNO<sub>3</sub>  $I_\alpha$ ,  $I_\beta$  complexes. All observed  $I_\alpha$ ,  $I_\beta$  bands are a few wavenumbers apart, which suggests that the two complexes have the same structure, but the geometry of their matrix environment is different. The concentration of the complex  $I_\beta$  increases after matrix annealing, which suggests that the complex is trapped in a more stable environment than the complex  $I_\alpha$ . The complex II is less stable and probably has different structure than the complexes  $I_\alpha$  and  $I_\beta$ . Unfortunately, we observed only one band due to the complex II (the absorption due to the  $\nu(\text{OH})$  stretching vibration), which does not allow us to draw conclusions about its structure.

The shifts of the HNO<sub>3</sub> (DNO<sub>3</sub>) fundamentals in  $I_\alpha$ ,  $I_\beta$  complexes clearly show that nitric acid is hydrogen bonded to C<sub>2</sub>H<sub>4</sub>. As expected, the most perturbed vibrations are the NOH group vibrations. The OH stretching fundamental is 300  $\text{cm}^{-1}$  red shifted, whereas the OH in plane bending and OH torsion modes are ca. 100, 150  $\text{cm}^{-1}$  blue shifted, respectively, upon complexation with C<sub>2</sub>H<sub>4</sub>. The magnitude of the relative shift  $\Delta\nu_s/\nu_o = 0.086$  of the perturbed OH stretching frequency is a good indicator of the strength of the hydrogen bond in a complex. In a set of complexes of nitric acid with various bases the strength of interaction depends on the proton affinity of a base. Barnes<sup>11</sup> has correlated the relative shifts,  $\Delta\nu_s/\nu_o$ , of the  $\nu(\text{OH})$  stretching frequency of HNO<sub>3</sub> in nitric acid complexes with various bases with the proton affinities of the bases. The  $\Delta\nu_s/\nu_o$  value for the nitric acid–ethylene complex correlates well with the proton affinity of C<sub>2</sub>H<sub>4</sub> [160 kJ mol<sup>-1</sup>]. Nitric acid is a stronger acid than HF and forms a substantially stronger complex with C<sub>2</sub>H<sub>4</sub> than HF, for which the  $\Delta\nu_s/\nu_o$  value is 0.056.

An interesting observation concerns the sensitivity of the perturbed OH fundamentals to the replacement of C<sub>2</sub>H<sub>4</sub> by C<sub>2</sub>D<sub>4</sub>. The  $\nu(\text{OH})$  and  $\nu(\text{OD})$  vibrations are red shifted by 2.7 and 1.9  $\text{cm}^{-1}$ , respectively, when C<sub>2</sub>H<sub>4</sub> is substituted by C<sub>2</sub>D<sub>4</sub> in the ethylene–HNO<sub>3</sub> complex. Due to the anharmonicity of the hydrogen bond stretching vibration or to the larger mass of C<sub>2</sub>D<sub>4</sub>, the average distance between HNO<sub>3</sub> and C<sub>2</sub>D<sub>4</sub> can be somewhat shorter than the distance between HNO<sub>3</sub> and C<sub>2</sub>H<sub>4</sub>, leading to larger shift. Such a trend was already observed for the NO–HX complexes<sup>23,24</sup> and for the H<sub>2</sub>O–NH<sub>3</sub> complexes.<sup>14</sup>

**TABLE 2: Observed Shifts (in  $\text{cm}^{-1}$ ) of the  $\nu_7$ ,  $\nu_{12}$  Fundamentals and of the  $\nu_7+\nu_8$  Combination Transition of C<sub>2</sub>H<sub>4</sub> in Its Complexes with H<sub>2</sub>O, HCl, HF, and HNO<sub>3</sub> Isolated in Argon Matrices**

	H <sub>2</sub> O <sup>14</sup>	HCl <sup>12</sup>	HF <sup>12</sup>	HNO <sub>3</sub> (this work)
$\nu_7$	12.2	10.1	25.5	26
$\nu_{12}$	1.1		0	2.4
$\nu_7+\nu_8$	16.9		38	38

As summarized in Table 1, other HNO<sub>3</sub> fundamentals are weakly perturbed upon complexation. In particular, the  $\nu_4$ , NO<sub>2</sub> symmetric stretching mode seems insensitive to complexation, which suggests that the NOH in plane bending coordinate does not contribute to this mode. The perturbed  $\nu_4$  mode is observed at ca. 1307  $\text{cm}^{-1}$  in all isotopically substituted complexes (HNO<sub>3</sub>–C<sub>2</sub>H<sub>4</sub>, HNO<sub>3</sub>–C<sub>2</sub>D<sub>4</sub>, DNO<sub>3</sub>–C<sub>2</sub>H<sub>4</sub>, HNO<sub>3</sub>–C<sub>2</sub>D<sub>4</sub>) and has a frequency value close to the nonperturbed  $\nu_4$  mode in the DNO<sub>3</sub> monomer. Upon HNO<sub>3</sub> complexation or in deuterated nitric acid, DNO<sub>3</sub>, there is decoupling between  $\delta(\text{OH})$  and  $\nu_s$ –(NO<sub>2</sub>) internal coordinates, and hence  $\nu_s(\text{NO}_2)$  appears at 1307  $\text{cm}^{-1}$  in the spectra of HNO<sub>3</sub> and DNO<sub>3</sub> complexes.

Due to the relatively weak hydrogen bonding in  $I_\alpha$ ,  $I_\beta$  complexes, the C<sub>2</sub>H<sub>4</sub> submolecule is only slightly perturbed by the nitric acid molecule. The most perturbed ethylene fundamental is the  $\nu_7$ , CH<sub>2</sub> out of plane wagging mode, which is blue shifted by 26  $\text{cm}^{-1}$  from the  $\nu_7$  mode of the C<sub>2</sub>H<sub>4</sub> monomer; only a 2.4  $\text{cm}^{-1}$  displacement toward higher frequencies is observed for the perturbed  $\nu_{12}$ , CH<sub>2</sub> in plane bending mode of the ethylene molecule in the complex. The significant perturbation of the  $\nu_7$  out of plane bending mode and very weak perturbation of the  $\nu_{12}$  in plane bending mode indicate that the OH group is bonded to the C<sub>2</sub>H<sub>4</sub>  $\pi$ -electron system in an out of plane position, a situation already encountered in all ethylene complexes studied so far. The combination band,  $\nu_7+\nu_8$ , is 38  $\text{cm}^{-1}$  blue shifted in the complex, suggesting ca. 12  $\text{cm}^{-1}$  blue shift for the infrared inactive  $\nu_8$  out of plane bending of C<sub>2</sub>H<sub>4</sub>. In the complex formed between C<sub>2</sub>H<sub>4</sub> and HF the HF molecule placed in an out of plane position to the ethylene molecule also exerts more perturbation on the  $\nu_7$  than on the  $\nu_8$  mode of C<sub>2</sub>H<sub>4</sub>.<sup>12</sup> No complex counterparts were observed for any of the infrared forbidden bands of C<sub>2</sub>H<sub>4</sub>. In Table 2 the complex shifts of C<sub>2</sub>H<sub>4</sub> fundamentals in ethylene complexes with nitric acid, hydric acids, and water are compared.

The obtained spectra indicate that in  $I_\alpha$ ,  $I_\beta$  complexes the OH group of nitric acid is bonded to the C<sub>2</sub>H<sub>4</sub>  $\pi$ -electron system in an out of plane position. The spectra do not provide information about mutual arrangement of the HNO<sub>3</sub> plane with respect to the C<sub>2</sub>H<sub>4</sub> plane, but the most stable structure is probably the structure in which the plane of the HNO<sub>3</sub> molecule is perpendicular to the C<sub>2</sub>H<sub>4</sub> plane and to the C=C bond of the ethylene molecule. One might expect that  $I_\alpha$ ,  $I_\beta$  complexes possess this kind of geometry. In the less stable complex II the plane of the HNO<sub>3</sub> molecule may be perpendicular to the C<sub>2</sub>H<sub>4</sub> plane but parallel to the C=C bond. Unfortunately, the obtained spectra do not provide information about mutual arrangement of C<sub>2</sub>H<sub>4</sub> and HNO<sub>3</sub> planes in the studied complexes.

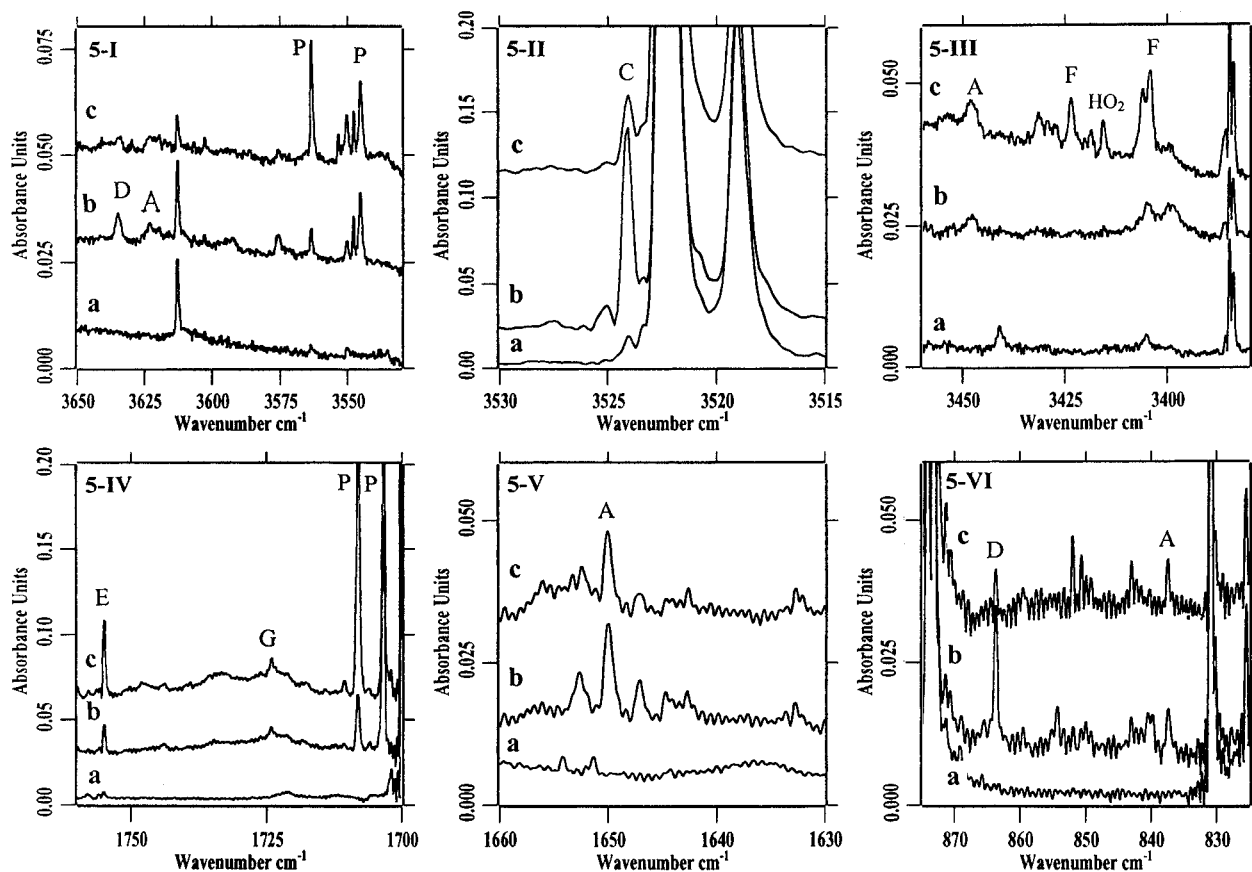

### 6. Photolysis of the Nitric Acid–Ethylene Complex

Two kinds of photolysis experiments were carried out after deposition of H(D)NO<sub>3</sub>/C<sub>2</sub>H<sub>4</sub>(D<sub>4</sub>)/Ar mixtures. In the first set of experiments the matrices were irradiated with the 266 nm laser line, whereas in the second set of experiments the full output of the mercury lamp was used. In the two cases the bands characteristic of the ethylene–nitric acid complex disappeared totally after 5 h irradiation time, whereas the absorptions due to the HNO<sub>3</sub> monomer decreased by 20%.

**TABLE 3: Product Absorptions (cm<sup>-1</sup>) Observed after Irradiation of the C<sub>2</sub>H<sub>4</sub>+HNO<sub>3</sub> System in an Argon Matrix**

<sup>a</sup> ↑, the band increases after matrix annealing; ↓, the band decreases after matrix annealing.

**Figure 5.** 3650–3530 cm<sup>-1</sup> (I), 3530–3515 cm<sup>-1</sup> (II), 3460–3380 cm<sup>-1</sup> (III), 1760–1700 cm<sup>-1</sup> (IV), 1660–1630 cm<sup>-1</sup> (V) and 875–825 cm<sup>-1</sup> (VI) regions in the spectra of the HNO<sub>3</sub>/C<sub>2</sub>H<sub>4</sub>/Ar = 1/1/500 matrix after deposition (a), after irradiation for 105 min with a 266 nm laser line (b), or after irradiation for 240 min with a Hg lamp (c).

In the gas phase the primary photolysis reaction of pure nitric acid by ultraviolet radiation proceeds via the channel  $\text{HNO}_3 + h\nu \rightarrow \text{HO} + \text{NO}_2$  with a quantum yield of 1.<sup>25</sup> In argon matrices the OH and NO<sub>2</sub> fragments recombine and form two different conformers of peroxyxynitrous acid HOONO.<sup>7,8</sup> Additional weak lines due to OH, HNO, NO, and NO<sub>2</sub> molecules and to the H<sub>2</sub>O...NO complex were also identified in argon matrices.<sup>7,8</sup> After irradiation of HNO<sub>3</sub>/C<sub>2</sub>H<sub>4</sub>/Ar matrices all these bands were

also observed. In addition, the bands characteristic of HO<sub>2</sub> and CO molecules and several bands that can be attributed to the products of the reaction of ethylene molecules with HNO<sub>3</sub> photofragments also appeared. Only the new product bands are reported and discussed.

Figure 5 compares the spectra obtained by irradiation of the HNO<sub>3</sub>/C<sub>2</sub>H<sub>4</sub>/Ar = 1/1/500 matrix with the 266 nm laser line and with the medium pressure mercury lamp. As illustrated in

Figure 5, the products formed after photolysis and their relative yields depend on the nature of the excitation source. The performed experiments allowed us to characterize seven different band sets that are formed with different yields on irradiation with a laser or mercury lamp and respond in different ways to prolonged photolysis and annealing processes. Absorptions labeled A (3623, 3448, 1650, 1647, 1259, 1106, 1036, 837, 616  $\text{cm}^{-1}$ ) and B (1565  $\text{cm}^{-1}$ ) are more intense in the laser experiment or are observed with comparable intensities in the laser and mercury lamp experiments, their intensities decrease after prolonged irradiation with the mercury lamp, and they show a small sensitivity to matrix annealing. The relative intensity of the B absorption with respect to A absorptions varies slightly in different experiments. The bands labeled C (3524, 2637.5, 1323, 888  $\text{cm}^{-1}$ ) and D (3635, 1194, 1096, 925, 864, 582  $\text{cm}^{-1}$ ) are much more intense in laser experiments than in mercury lamp experiments; the C absorptions appear as weak bands after matrix irradiation with the mercury lamp, whereas the D absorptions are still weaker or are not observed at all. Both C and D bands disappear after matrix annealing. The bands labeled E (1755  $\text{cm}^{-1}$ ), F (3419, 3404.5, 1407, 1395  $\text{cm}^{-1}$ ), and G (3550, 3342, 2826, 1791, 1724, 1246, 1130, 1076, 843, 790  $\text{cm}^{-1}$ ) appear with larger intensity in mercury lamp experiments than in the laser experiment. The 1755  $\text{cm}^{-1}$  band is shifted after matrix annealing to 1750.5  $\text{cm}^{-1}$ ; no other product absorption was identified that had the same relative intensity with respect to the E band in all performed experiments. The intensities of the F bands decrease, whereas the intensities of the G bands increase after prolonged photolysis; both F and G bands grow in intensity after matrix annealing.

Identification of the photolysis products from the observed bands is not straightforward. First, each group of bands may correspond to one or several products formed either as primary or secondary photolysis products. Second, due to the low yield of the reaction products, only the most intense absorptions characteristic of the products formed during photolysis are observed. The possibility of formation of the complexes between photolysis products and ethylene also has to be taken into account.

The bands labeled A are tentatively assigned to  $\text{HOH}_2\text{C}-\text{CH}_2\text{ONO}$ , ethylene glycol nitrite, as is now discussed. The 3623, 3448  $\text{cm}^{-1}$  bands are characteristic of the  $\nu(\text{OH})$  stretching vibrations. The 1259  $\text{cm}^{-1}$  band may be attributed to the  $\delta(\text{COH})$  bending vibration; its deuterium counterpart was identified at 916  $\text{cm}^{-1}$ , which gives an isotopic shift ratio 1259/916 = 1.37 and confirms the band assignment. The bands observed at 1650, 1647, 837, and 616  $\text{cm}^{-1}$  demonstrate the presence of the  $\text{O}-\text{N}=\text{O}$  group in species A. In the spectra of *trans*-methyl nitrite isolated in an argon matrix the  $\nu(\text{N}=\text{O})$  and  $\nu(\text{N}-\text{O})$  stretching and  $\delta(\text{ONO})$  bending vibrations were observed, respectively, at 1666, 809, and 565  $\text{cm}^{-1}$  and in the spectra of *cis*-methyl nitrite at 1617, 839, and 624  $\text{cm}^{-1}$ .<sup>26,27</sup> The 1036  $\text{cm}^{-1}$  absorption observed for species A may be due to the  $\nu(\text{C}-\text{ONO})$  stretching vibration; the corresponding vibrations were observed at 1043 and 987  $\text{cm}^{-1}$  for *trans*- and *cis*-methyl nitrite isomers, respectively. The 1106  $\text{cm}^{-1}$  band appears in the region of the  $\nu(\text{CCO})$  asymmetric stretching vibration of *trans*-ethanol (1091.7  $\text{cm}^{-1}$ ).<sup>28</sup> The bands observed for species A correspond to the vibrations that are characteristic for ethylene glycol nitrite and that are expected to give rise to the strongest absorptions in the spectrum of this molecule. The two bands observed in the  $\nu(\text{OH})$  stretching region may be due to different conformers of ethylene glycol nitrite, but identification of one band only in the  $\delta(\text{COH})$  and  $\nu(\text{N}-\text{O})$  regions does not support this assignment. Another possibility is that the lower frequency band at 3448  $\text{cm}^{-1}$  is due to an intermolecular complex between

A species and another photolysis product; the possibility that one of the two  $\nu(\text{OH})$  bands belongs to another species and not to ethylene glycol nitrite also cannot be excluded. The very low yield of the A product and strong sensitivity of the frequencies and intensities of the  $\nu(\text{OH})$  bands to any perturbation of the OH stretch mode make identification and assignment of the bands occurring in the OH stretch region particularly difficult. However the whole set of A bands allows us to tentatively identify ethylene glycol nitrite in the studied matrices. Ethylene glycol nitrite can be formed as the primary photolysis product in double-addition reaction of OH and ONO radicals to the  $\text{C}=\text{C}$  bond of the ethylene molecule.

The 1565  $\text{cm}^{-1}$ , B band appears in the vicinity of the 1562  $\text{cm}^{-1}$   $\nu_2(\text{N}=\text{O})$  stretching vibration of the HNO radical, which suggests that the band may be due to the complexed HNO radical. In this region may appear the  $\nu(\text{N}=\text{O})$  stretching vibration of the nitrosyl group and the asymmetric stretching  $\nu(\text{NO}_2)$  vibration of the nitro group. Double-addition reaction of OH and  $\text{NO}_2$  photofragments to the  $\text{C}=\text{C}$  bond would lead to formation of 2-nitroethanol, but this is excluded on the basis of the following reasons. The spectra of the  $\text{HOH}_2\text{C}-\text{CH}_2-\text{NO}_2$  molecule isolated in an argon matrix reveal two intense absorptions at 1570 and 1373.9  $\text{cm}^{-1}$  due to the asymmetric stretch  $\text{NO}_2$  vibration and to the coupled symmetric stretch  $\text{NO}_2$  and COH bending vibrations.<sup>29</sup> The absence in our spectra of one of two most characteristic vibrations of the 2-nitroethanol molecule indicates that this molecule is not the primary photoproduct of the nitric acid-ethylene reaction.

All four C bands at 3524, 2637, 1323, and 888  $\text{cm}^{-1}$  appear, respectively, in the vicinity of the 3522.3, 2635.5, 1321.4, and 897.0  $\text{cm}^{-1}$   $\text{HNO}_3$  monomer absorptions. The bands disappear after matrix annealing. So, the species can be identified with confidence as the  $\text{HNO}_3$  monomer in an unstable site or weakly perturbed by another photolysis product.

The identification of D species is not straightforward. The D bands (3635, 1194, 1096, 925, 864, 582  $\text{cm}^{-1}$ ) appear with reasonable yield in the laser experiment and are extremely weak or are not observed at all in mercury lamp experiments, the bands are very sensitive to matrix annealing. The 3635  $\text{cm}^{-1}$  band characteristic of the  $\nu(\text{OH})$  stretch vibration proves the presence of an OH group in the species D. The 1096, 864  $\text{cm}^{-1}$  bands are observed at frequency values close to the absorptions corresponding to CCO asymmetric and symmetric stretching vibrations of *trans*-ethanol (1091.7, 886.7  $\text{cm}^{-1}$ ).<sup>28</sup> The 1194  $\text{cm}^{-1}$  band may be due to the  $\delta(\text{COH})$  bending vibration which is expected to occur in this region of the spectrum. The absorption at 582  $\text{cm}^{-1}$  may be attributed to a  $\text{CH}_2$  rocking vibration; in the spectrum of the  $\text{CH}_2\text{OH}$  radical the corresponding absorption was observed at 569  $\text{cm}^{-1}$ . No absorption characteristic of D species was identified in the 1670–1500  $\text{cm}^{-1}$  region, which suggests an absence of the nitro, nitrite, and nitroso groups in the species D; the  $\text{NO}_2$ ,  $\text{O}-\text{N}=\text{O}$ , and  $-\text{N}=\text{O}$  groups all give rise to strong absorption in this region of the spectrum. The gas phase studies of the reaction of OH with ethylene demonstrated that at low temperatures the reaction mechanism is dominated by electrophilic addition of OH to the double bond.<sup>30</sup> So, the species D is tentatively identified as the  $\text{HOH}_2\text{C}=\text{CH}_2$  radical.

The E, F, and G species appear with higher yield when the matrices are irradiated with output of the mercury lamp. The species E is characterized by one band only observed at 1755  $\text{cm}^{-1}$ ; no other bands in the studied spectra were found to have the same relative intensity with respect to the 1755  $\text{cm}^{-1}$  absorption in the performed experiments. The band is stronger in mercury lamp experiments but is also well-defined in laser experiments. The 1755  $\text{cm}^{-1}$  absorption occurs in the  $\text{C}=\text{O}$

stretch region and suggests the presence of a  $-\text{CHO}$  group in species E; the  $\text{C}=\text{O}$  stretch vibrations of formaldehyde and acetaldehyde in argon matrices are observed in this region of the spectrum.<sup>31,32</sup> Lack of any other band accompanying the  $1755\text{ cm}^{-1}$  absorption suggests that species E does not involve groups that give rise to characteristic, intense bands of intensity comparable to the  $\text{C}=\text{O}$  stretch absorption (like  $\text{COH}$ ,  $\text{NO}_2$ ,  $\text{NO}$ ,  $\text{ONO}$ ). In the  $\text{C}_2\text{D}_4/\text{HNO}_3$  experiment the counterpart of the  $1755\text{ cm}^{-1}$  band was identified at  $1742.3\text{ cm}^{-1}$ . The  $13.7\text{ cm}^{-1}$  isotopic shift of the  $1755\text{ cm}^{-1}$  absorption suggests that the band may be due to the  $\text{C}=\text{O}$  stretch vibration in a perturbed acetaldehyde molecule and rather excludes its assignment to formaldehyde. The  $44.2\text{ cm}^{-1}$  deuterium isotopic shift was observed for the  $\text{C}=\text{O}$  stretch vibration in formaldehyde, whereas the ca.  $10\text{ cm}^{-1}$  deuterium isotopic shift was found for the corresponding vibration in acetaldehyde.<sup>31,32</sup> Acetaldehyde is one of the probable decomposition products of the energized  $\text{HOH}_2\text{C}-\text{CH}_2$  radical. The studies of the reaction of OH with ethylene in discharge flow reactors indicated the formation of the following products:  $\text{HOCH}_2\text{CH}_2$ ,  $\text{CH}(\text{OH})\text{-Me}$ ,  $\text{MeCHO}$  and  $\text{H}$ , and  $\text{HCHO}$  and  $\text{Me}$ .<sup>33</sup> The larger intensity of the  $1755\text{ cm}^{-1}$  band in the mercury lamp experiment than in the laser experiment supports an identification of the acetaldehyde molecule as a decomposition product of the  $\text{HOH}_2\text{C}-\text{CH}_2$  radical; the low yield of the radical in the mercury lamp experiment is most probably due to its photodecomposition. The acetaldehyde molecule formed in decomposition reaction of the  $\text{HOCH}_2\text{CH}_2$  radical may be trapped in an unstable site, and the shift of the  $1755\text{ cm}^{-1}$  band to  $1750.5\text{ cm}^{-1}$  after matrix annealing may be due to the change of site geometry or to the complex formation between the acetaldehyde molecule and another molecule present in the matrix.

The species F is tentatively identified as peroxyxynitrous acid,  $\text{HOONO}$ , complexed with the ethylene molecule. The bands observed at  $3404.5$ ,  $3419\text{ cm}^{-1}$  are assigned to perturbed OH stretch vibrations of *cis-perp*- $\text{HOONO}$  (PB) and *trans-perp*- $\text{HOONO}$  (PA) conformers; the corresponding bands are observed at  $3545.5$  (PB) and  $3563.3\text{ cm}^{-1}$  (PA) for  $\text{HOONO}$  monomers. The two bands show  $141$  (PB),  $144$  (PA)  $\text{cm}^{-1}$  red shifts when the two  $\text{HOONO}$  conformers are complexed with  $\text{C}_2\text{H}_4$ . For comparison the OH stretch vibrations of  $\text{HNO}_3$ , *trans*- $\text{HONO}$ , and *cis*- $\text{HONO}$  are ca.  $220$ ,  $137$ , and  $103\text{ cm}^{-1}$  red shifted when the respective molecules are complexed to ethylene. The  $3404.5\text{ cm}^{-1}$  band observed in  $\text{C}_2\text{H}_4/\text{HNO}_3$  experiments is shifted to  $3402.5\text{ cm}^{-1}$  in  $\text{C}_2\text{D}_4/\text{HNO}_3$  experiments (the deuterium counterpart of the  $3419\text{ cm}^{-1}$  band was not observed), as expected for the band due to the  $-\text{OH}$  group hydrogen bonded to  $\text{C}_2\text{H}_4$ ,  $\text{C}_2\text{D}_4$  molecules. As was discussed earlier in this paper, the OH stretches of perturbed  $\text{HNO}_3$  are observed at  $3307.4$ ,  $3300.8\text{ cm}^{-1}$  for the  $\text{HNO}_3 \cdots \text{C}_2\text{H}_4$  complex and are red shifted to  $3304.7$ ,  $3297.8\text{ cm}^{-1}$  for the  $\text{HNO}_3 \cdots \text{C}_2\text{D}_4$  complex. In the  $\text{C}_2\text{D}_4/\text{DNO}_3$  experiment the counterparts of the  $3419$ ,  $3404.5\text{ cm}^{-1}$  absorptions were identified at  $2527$ ,  $2519.0\text{ cm}^{-1}$ , respectively. The isotopic shift ratios,  $3404.5/2519.0 = 1.35$  and  $3419/2527 = 1.35$ , support the assignment of the  $3404.5$ ,  $3419\text{ cm}^{-1}$  bands. The  $1407$ ,  $1395.0\text{ cm}^{-1}$  absorptions occurring in  $\text{C}_2\text{H}_4/\text{HNO}_3$  experiments are tentatively assigned to perturbed HOO bending vibrations of *trans-perp* (PA) and *cis-perp* (PB)  $\text{HOONO}$  conformers bonded to the ethylene molecule. The  $1407$ ,  $1395\text{ cm}^{-1}$  bands are  $35$  and  $31\text{ cm}^{-1}$  blue shifted from the corresponding bands of  $\text{HOONO}$  monomers. In  $\text{C}_2\text{H}_4/\text{DNO}_3$  experiments their corresponding counterparts were identified at  $1145$ ,  $1141\text{ cm}^{-1}$ , which leads to isotopic shift ratios ( $1.23$ ,  $1.22$ , respectively) of values similar to those characteristic of the corresponding vibrations of  $\text{HOONO}$  monomers ( $1364.1/1089.7 = 1.25$  for PB and  $1772.5/$

$1091.7 = 1.26$  for PA). Unfortunately, no perturbed  $\nu_7$  mode of the ethylene molecule was identified for the  $\text{C}_2\text{H}_4 \cdots \text{HOONO}$  complex. This may be due to the possibility that the  $\nu_7$ ,  $\text{C}_2\text{H}_4$  absorption for this complex is weaker than the absorptions due to the perturbed  $\text{HOONO}$  modes. In the spectra of the studied  $\text{C}_2\text{H}_4 \cdots \text{HNO}_3$  complex and in the spectra of the previously reported  $\text{C}_2\text{H}_4 \cdots \text{HF}$ ,<sup>12</sup>  $\text{C}_2\text{H}_4 \cdots \text{HONO}$ <sup>34</sup> complexes the band due to the  $\nu_7$  mode of bonded  $\text{C}_2\text{H}_4$  was found to be ca. 4 times weaker than the band due to bonded OH or HF groups. The possibility that the band due to the  $\nu_7$ ,  $\text{C}_2\text{H}_4$  mode of the  $\text{C}_2\text{H}_4 \cdots \text{HOONO}$  complex coincides with the corresponding absorption of the  $\text{C}_2\text{H}_4 \cdots \text{HNO}_3$  complex also has to be taken into account. Thus, a very low yield of the  $\text{C}_2\text{H}_4 \cdots \text{HOONO}$  complex in the studied matrices, the relatively small intensity of the  $\nu_7$   $\text{C}_2\text{H}_4$  band as compared to the  $\nu(\text{OH})$  band, and the possibility of coincidence of the perturbed  $\nu_7$ ,  $\text{C}_2\text{H}_4$  absorptions for the  $\text{C}_2\text{H}_4 \cdots \text{HOONO}$ ,  $\text{C}_2\text{H}_4 \cdots \text{HNO}_3$  complexes seem to be a reasonable explanation of the fact that we do not observe in the studied spectra the absorption due to the  $\nu_7$  mode of  $\text{C}_2\text{H}_4$  complexed with the  $\text{HOONO}$  molecule.

The bands corresponding to G species are more intense in the mercury lamp experiment; their intensities increase with prolonged photolysis and after matrix annealing, which suggests that they are due to secondary photolysis products. They probably correspond to more than one product; due to their weak intensity, it was difficult to estimate the relative intensity of the G bands in different experiments. The  $3342$ ,  $1724$ ,  $1246$ ,  $1130$ ,  $1076$ , and  $843\text{ cm}^{-1}$  bands have frequency values close to the  $3300$ ,  $1748.2$ ,  $1270$ ,  $1116.5$ ,  $1075$ , and  $863.5\text{ cm}^{-1}$  bands observed for glycoaldehyde.<sup>35</sup> The hydrogen-bonded complex between glycoaldehyde and  $\text{HNO}$  could be the photolysis product of energized ethylene glycol nitrite:  $[\text{HOH}_2\text{C}-\text{CH}_2-\text{ONO}]^* \Rightarrow \text{HOH}_2\text{CCHO} \cdots \text{HNO}$ . The relatively large shifts of the observed bands from the glycoaldehyde monomer bands may be justified by the replacement of an intramolecular hydrogen bond by an intermolecular hydrogen bond to  $\text{HNO}$ . The photolysis studies of methyl nitrite in low-temperature matrices have shown that the photodecomposition product of  $\text{CH}_3\text{ONO}$  is a hydrogen-bonded complex between  $\text{H}_2\text{CO}$  and  $\text{HNO}$ .<sup>36</sup> The obtained spectra suggest that the  $3342\text{ cm}^{-1}$  band observed in the  $\text{C}_2\text{H}_4+\text{HNO}_3$  experiment and tentatively assigned to the  $\nu(\text{OH})$  vibration of glycoaldehyde is shifted to  $2475\text{ cm}^{-1}$  both in  $\text{C}_2\text{D}_4+\text{HNO}_3$  and  $\text{C}_2\text{D}_4+\text{DNO}_3$  experiments. This indicates a rather complex photoprocess by which  $\text{HOH}_2\text{CCHO} \cdots \text{HNO}$  is formed. It is known that in the primary photodissociation reaction of  $\text{CH}_3\text{ONO}$  the  $\text{CH}_3\text{O}$  and  $\text{NO}$  radicals are formed, which may further react to form the  $\text{H}_2\text{CO} \cdots \text{HNO}$  complex.<sup>37</sup> Thus, it is not excluded that in the primary photodissociation reaction of ethylene glycol nitrite the  $\text{OHH}_2\text{CCH}_2\text{O}$  and  $\text{NO}$  radicals are produced ( $\text{HOH}_2\text{CCH}_2\text{ONO} \Rightarrow \text{HOH}_2\text{CCH}_2\text{O} + \text{NO}$  or  $\text{HOD}_2\text{CCD}_2\text{ONO} \Rightarrow \text{HOD}_2\text{CCD}_2\text{O} + \text{NO}$ ). The shift of the  $3342\text{ cm}^{-1}$  band observed in the  $\text{C}_2\text{H}_4+\text{HNO}_3$  to  $2475\text{ cm}^{-1}$  in  $\text{C}_2\text{D}_4+\text{HNO}_3$  experiment suggests that this is the hydrogen atom of the OH group that reacts with  $\text{NO}$  to form the  $\text{DOD}_2\text{CCDO} \cdots \text{HNO}$  complex. Intuitively it might be expected that in the abstraction reaction of the hydrogen atom from the  $\text{HOD}_2\text{CCD}_2\text{O}$  radical an oxygen-bridged species is formed:

Unfortunately, due to the very low yield of the G product, the above considerations are speculative.

**Mechanism of Photolysis.** The main products formed on photolysis of  $\text{HNO}_3/\text{C}_2\text{H}_4/\text{Ar}$  matrices are peroxyxynitrous acid,

OH, and NO<sub>2</sub>, i.e. the products of HNO<sub>3</sub> photolysis in solid argon. This is confirmed by high relative intensity ratios of peroxyntrous acid absorptions with respect to the bands tentatively assigned to the products formed in reaction of HNO<sub>3</sub> photofragments with C<sub>2</sub>H<sub>4</sub>. So, most of the OH and NO<sub>2</sub> fragments, formed in the photodissociation process of the HNO<sub>3</sub>-C<sub>2</sub>H<sub>4</sub> complex and trapped in one matrix cage with the C<sub>2</sub>H<sub>4</sub> molecule, recombine and form HNO<sub>3</sub> and HOONO. These processes explain the formation of an unstable site for the HNO<sub>3</sub> molecule (C species) as well as the formation of the C<sub>2</sub>H<sub>4</sub>-HOONO complex (F species). The HNO<sub>3</sub> molecule recombined from OH and NO<sub>2</sub> photofragments may be oriented in such a way with respect to the C<sub>2</sub>H<sub>4</sub> molecule trapped in the same matrix cage that the C<sub>2</sub>H<sub>4</sub>-HNO<sub>3</sub> complex is reproduced. If, however, the orientation of the recombined HNO<sub>3</sub> molecule does not favor the hydrogen bond interaction between the two molecules, then the HNO<sub>3</sub> molecule is trapped in unstable geometrical arrangement (i.e. in an unstable site). In a similar way the HOONO molecule formed by recombination of OH and NO<sub>2</sub> may interact with the C<sub>2</sub>H<sub>4</sub> molecule trapped in the same cage, forming the C<sub>2</sub>H<sub>4</sub>-HOONO complex.

The absorptions of the products formed in addition reactions of OH and NO<sub>2</sub> photofragments to the ethylene molecule allowed us to only tentatively identify the reaction products. The obtained results suggest that ethylene glycol nitrite (A species) is formed in a double-addition reaction of OH and NO<sub>2</sub> to the C=C bond of ethylene. The A species is not sensitive to matrix annealing and decomposes on prolonged photolysis, as expected for ethylene glycol nitrite molecules. Ethylene glycol nitrite may photolyze to glycoaldehyde and HNO; the photolysis studies of methyl nitrite in low-temperature matrices have shown that the primary photodecomposition product of CH<sub>3</sub>ONO is the H<sub>2</sub>CO-HNO hydrogen-bonded complex.<sup>35</sup>

The analysis of the obtained results also suggests that in a single-addition reaction of the OH radical to the C<sub>2</sub>H<sub>4</sub> molecule the HOH<sub>2</sub>CCH<sub>2</sub> radical (D species) is formed. But the identification of this radical is rather tentative, as the bands assigned to the radical are very weak and the performed isotopic studies are only fragmentary. The infrared spectra of the HOH<sub>2</sub>-CCH<sub>2</sub> species have not been reported so far. The higher concentration of the radical in laser experiments than in mercury lamp experiments can be readily explained by the fact that the radical decomposes easily when photolyzed with broad band output of the mercury lamp. The possible product of photolytic decomposition of HOH<sub>2</sub>CCH<sub>2</sub> is CH<sub>3</sub>CHO (species E).

## 7. Conclusions

Infrared studies of the HNO<sub>3</sub>-C<sub>2</sub>H<sub>4</sub> system and its deuterated isotopomers in argon matrices indicate the existence of a stable 1/1  $\pi$ -electron hydrogen-bonded HNO<sub>3</sub>...C<sub>2</sub>H<sub>4</sub> complex in two trapping sites. Eight perturbed HNO<sub>3</sub> vibrations and two perturbed C<sub>2</sub>H<sub>4</sub> vibrations were identified for the complexes trapped in the two sites. The spectroscopic analysis of the complexes proves that in the stable 1/1 complexes the OH group is bonded to the  $\pi$ -electron system in an out of plane position. The spectra also indicate an existence of a less stable 1/1 complex.

The main products of photolysis of nitric acid/ethylene/argon matrices are nitric acid and peroxyntrous acid, i.e. the same products that are formed on photolysis of nitric acid/argon matrices, which means that most of the OH and NO<sub>2</sub> photofragments recombine and do not react with the C<sub>2</sub>H<sub>4</sub> molecule.

Peroxyntrous acid forms a hydrogen-bonded complex with ethylene molecules trapped in the same matrix cage. The new major photolysis product of the C<sub>2</sub>H<sub>4</sub>-HNO<sub>3</sub> complex is ethylene glycol nitrite, which is formed in a double-addition reaction of OH and NO<sub>2</sub> photofragments to ethylene. The spectra also suggest the formation of the HOH<sub>2</sub>CCH<sub>2</sub> radical in a single-addition reaction of OH to ethylene.
