Chloro-aquachromium(III) tetraphenylporphyrin,  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$ , reversibly reacts with isocyanide,  $\text{CN}-\text{R}$ , to form  $\text{Cl}(\text{CN}-\text{R})\text{Cr}^{\text{III}}\text{TPP}$  in toluene solutions containing  $4.4 \times 10^{-3}$  M  $\text{H}_2\text{O}$  and  $\text{CN}-\text{R}$ . The equilibrium constant for the formation of  $\text{Cl}(\text{CN}-\text{R})\text{Cr}^{\text{III}}\text{TPP}$  obtained by spectroscopic measurements ranges from 10 to  $10^2$  depending on the nature of the isocyanide used. The laser-photolysis studies of the toluene solution demonstrate that  $\text{CN}-\text{R}$  is photodissociated from  $\text{Cl}(\text{CN}-\text{R})\text{Cr}^{\text{III}}\text{TPP}$  to produce  $\text{ClCr}^{\text{III}}\text{TPP}$  with a quantum yield ca. 0.1. The five-coordinate  $\text{ClCr}^{\text{III}}\text{TPP}$  reacts with  $\text{H}_2\text{O}$  and  $\text{CN}-\text{R}$  to give  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  and  $\text{Cl}(\text{CN}-\text{R})\text{Cr}^{\text{III}}\text{TPP}$ , respectively. The transient product  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  further reacts with  $\text{CN}-\text{R}$  to regenerate  $\text{Cl}(\text{CN}-\text{R})\text{Cr}^{\text{III}}\text{TPP}$ . The rates for the decay of  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  are measured as a function of the concentration of  $\text{CN}-\text{R}$  in order to determine the rate constants of the forward and backward reactions for the formation of  $\text{Cl}(\text{CN}-\text{R})\text{Cr}^{\text{III}}\text{TPP}$ . The equilibrium constants obtained from the kinetic analysis for the decay of  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  are in good agreement with those determined by spectroscopic measurements. The mechanism for the equilibrium reaction is discussed in detail on the basis of the rate constants for the formation of  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  and  $\text{Cl}(\text{CN}-\text{R})\text{Cr}^{\text{III}}\text{TPP}$  from  $\text{ClCr}^{\text{III}}\text{TPP}$ , measured in the temperature range 200–300 K. The quantum yield for the photodissociation of  $\text{CN}-\text{R}$  is not affected by the presence of oxygen. Since the lowest excited state  ${}^6\text{T}_1$  of  $\text{Cl}(\text{CN}-\text{R})\text{Cr}^{\text{III}}\text{TPP}$  observed by laser photolysis is effectively quenched by oxygen, this state is not responsible for the ligand ejection from  $\text{Cl}(\text{CN}-\text{R})\text{Cr}^{\text{III}}\text{TPP}$ . The  ${}^4\text{S}_1$  state is assumed to be the reactive excited state of  $\text{Cl}(\text{CN}-\text{R})\text{Cr}^{\text{III}}\text{TPP}$ .

## Introduction

The excited states of chromium(III) porphyrins have been well studied both theoretically and experimentally.<sup>1,2</sup> According to the theoretical consideration,<sup>1</sup> the central chromium(III) atom<sup>3</sup> having a spin state  $S = 3/2$  interacts with the porphyrin  $\pi$  system in the excited states to give the  ${}^4\text{S}_1$ ,  ${}^2\text{T}_1$ ,  ${}^4\text{T}_1$ ,  ${}^6\text{T}_1$  states. The first one and the last three are, respectively, produced by a coupling of the central chromium atom ( $S = 3/2$ ) to the lowest excited singlet and the triplet state of the porphyrin  $\pi$  system.<sup>1</sup> The studies on the emission from the chromium(III) porphyrins have shown that the  ${}^4\text{T}_1$  and  ${}^6\text{T}_1$  states are in equilibrium because of the small energy difference between them.

The axial ligand significantly affects the electronic structure and the reactivity of metalloporphyrins in either the ground and excited states.<sup>2</sup> The laser-photolysis studies of chlorochromium(III) tetraphenylporphyrins,  $\text{Cl}(\text{L})\text{Cr}^{\text{III}}\text{TPP}$  (L = sixth axial ligand), have revealed that the yields for photodissociation of the axial ligands markedly depend on the nature of L.<sup>4–7</sup> For instance,  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  photodissociates the axial  $\text{H}_2\text{O}$  with a quantum yield  $\Phi = 0.98$ ,<sup>7</sup> while  $\text{Cl}(\text{CH}_3\text{COCH}_3)\text{Cr}^{\text{III}}\text{TPP}$  photochemically releases the axial acetone with  $\Phi = 0.15$ .<sup>4</sup> The excited state responsible for the photodissociation of the sixth ligand is assumed to be the  ${}^4\text{S}_1$  state of the chromium(III)

porphyrin. Others,  ${}^2\text{T}_1$ ,  ${}^4\text{T}_1$ , and  ${}^6\text{T}_1$ , are independent of the photodissociation of the axial ligands.<sup>4–7</sup>

$\text{ClCr}^{\text{III}}\text{TPP}$  synthesized has a water molecule at the axial position as revealed by X-ray structure determination.<sup>6</sup> The addition of isocyanide ( $\text{CN}-\text{R}$ ) into a toluene solution of  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  yields the isocyanide complexes  $\text{Cl}(\text{CN}-\text{R})\text{Cr}^{\text{III}}\text{TPP}$ . The present paper describes the absorption spectroscopic and laser-photolysis studies of  $\text{Cl}(\text{CN}-\text{R})\text{Cr}^{\text{III}}\text{TPP}$  in toluene. The complex  $\text{Cl}(\text{CN}-\text{R})\text{Cr}^{\text{III}}\text{TPP}$  photodissociates  $\text{CN}-\text{R}$  by laser photolysis to yield the five-coordinate  $\text{ClCr}^{\text{III}}\text{TPP}$ . The reactive excited state for photodissociation and the association mechanisms of  $\text{CN}-\text{R}$  to both  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  and the five-coordinate  $\text{ClCr}^{\text{III}}\text{TPP}$  are discussed on the basis of the laser-photolysis studies carried out in the temperature range 300–200 K.

## Experimental Section

Toluene was supplied from Wako Pure Chemicals Industry Ltd. The concentration of water in toluene used in the present study is  $4.4 \times 10^{-3}$  M. The isocyanides used were  $\text{CN}-\text{R}^n$  ( $n = 1-5$ ; see Chart 1), which were synthesized according to literature.<sup>8–10</sup> Chloro-aquachromium(III) tetraphenylporphyrin,  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$ , was synthesized and purified by the method reported in ref 3. The concentration of  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  in toluene is ca.  $10^{-5}$  M during the course of this study. The sample quartz cells have an optical path length of 1 cm.

**Figure 1.** Absorption spectral changes observed for  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  in a toluene solution containing  $4.4 \times 10^{-3}$  M  $\text{H}_2\text{O}$  and  $\text{CN-R}^1$ . The concentrations of  $\text{CN-R}^1$  are (1) 0, (2)  $1.11 \times 10^{-5}$ , (3)  $2.22 \times 10^{-5}$ , (4)  $4.44 \times 10^{-5}$ , (5)  $1.11 \times 10^{-4}$ , (6)  $2.22 \times 10^{-4}$ , (7)  $5.55 \times 10^{-4}$ , and (8)  $1.0 \times 10^{-2}$  M.

### CHART 1

Absorption spectra were recorded on a Hitachi 330 spectrophotometer. Laser-photolysis studies were carried out with the use of a Nd:YAG laser equipped with the second (532 nm), third (355 nm), and fourth (266 nm) harmonic generators. The duration and the energy of a laser pulse at 355 nm were, respectively, 20 ns and 60 mJ/pulse. The detection system of the transient is described elsewhere.<sup>11</sup> The temperatures of the sample solutions were controlled with the use of an Oxford cryostat (model DN 1007).

### Results

**Absorption Spectroscopic Studies of Isocyanide Complexes.** Figure 1 shows the absorption spectral changes observed for  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  in the toluene solution with a change in the concentration of  $\text{CN-R}^1$ . The absorption peaks of  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  located at 394, 448, and 562 nm decrease in intensity, and new peaks appear at 427, 474, 585, and 628 nm with an increase in the concentration of the  $\text{CN-R}^1$ . Clear isosbestic points observed in the spectra indicate that the spectral changes are interpreted in terms of the equilibrium reaction

The equilibrium constant  $K$  ( $=k_f/k_b$ ) is expressed as

$$K = \frac{[\text{Cl}(\text{CN-R}^1)\text{Cr}^{\text{III}}\text{TPP}][\text{H}_2\text{O}]}{[\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}][\text{CN-R}^1]} \quad (2)$$

**Figure 2.** Transient absorption spectrum observed for the toluene solution of  $\text{Cl}(\text{CN-R}^1)\text{Cr}^{\text{III}}\text{TPP}$  in the presence of  $1.13 \times 10^{-3}$  M  $\text{CN-R}^1$  at 300 K. The spectrum was taken at 1.0  $\mu\text{s}$  after 355-nm laser pulsing. The short-lived species completely disappeared within 1.0  $\mu\text{s}$  after pulsing (data not shown).

Equation 3 is derived from eqs 1 and 2:

$$Y = \frac{(D - D_0)}{(D_\infty - D)} = K \frac{[\text{CN-R}^1]}{[\text{H}_2\text{O}]} \quad (3)$$

Here,  $D$  is the absorbance at  $[\text{CN-R}^1]$ , and  $D_0$  and  $D_\infty$  stand for the absorbances at  $[\text{CN-R}^1] = 0$  and at an "infinite" concentration of  $\text{CN-R}^1$ , respectively. The plot of  $Y$  vs  $[\text{CN-R}^1]$  gives a straight line with an intercept at the origin. The slope of the line gives  $K/[\text{H}_2\text{O}] = 2.9 \times 10^4 \text{ M}^{-1}$ . The concentration of water in toluene is  $4.4 \times 10^{-3}$  M, and thus, the equilibrium constant  $K$  is determined as  $1.28 \times 10^2$ .

The absorption spectrum of  $\text{Cl}(\text{CN-R}^1)\text{Cr}^{\text{III}}\text{TPP}$  exhibits characteristic features particularly in the Soret band region. The absorption band of  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  located at 448 nm splits into two bands with intensity similar to each other by forming the isocyanide complex, one at 427 and another at 474 nm. The molar absorption coefficients of  $\text{Cl}(\text{CN-R}^1)\text{Cr}^{\text{III}}\text{TPP}$  in toluene are determined as  $6.4 \times 10^4 \text{ M}^{-1}\text{cm}^{-1}$  at 427 nm and  $6.6 \times 10^4 \text{ M}^{-1}\text{cm}^{-1}$  at 474 nm. These values are smaller than that ( $2.33 \times 10^5 \text{ M}^{-1}\text{cm}^{-1}$ ) of  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  at 448 nm. The spectra, the peak wavelengths, and the molar absorption coefficients obtained for the five isocyanide complexes in the Soret band region are very close each other, independent of the nature of the isocyanide studied.

**Laser-Photolysis Studies.** The laser-photolysis studies were carried out for the toluene solution of  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  in the presence of  $1.13 \times 10^{-3}$  M  $\text{CN-R}^1$  at 300 K. The major chromium porphyrin species (>99.9%) in the solution was confirmed to be  $\text{Cl}(\text{CN-R}^1)\text{Cr}^{\text{III}}\text{TPP}$ . The transient spectrum observed at 300 K shows that short- and long-lived species are produced; the former decays within 1.0  $\mu\text{s}$  after pulsing and the latter over a few tens of microseconds. We initially describe the kinetic study of the long-lived species. The short-lived species will be mentioned later.

Figure 2 shows the long-lived transient absorption spectrum measured at 1.0  $\mu\text{s}$  after pulsing. The transient spectrum has a positive peak at 448 nm and a negative one at 480 nm. The spectrum is in good agreement with the difference spectrum obtained by subtracting the spectrum of  $\text{Cl}(\text{CN-R}^1)\text{Cr}^{\text{III}}\text{TPP}$  from that of  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$ . Thus, the laser photolysis of  $\text{Cl}(\text{CN-R}^1)\text{Cr}^{\text{III}}\text{TPP}$  is concluded to yield  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$ . The decay of the transient  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  strictly follows first-

**Figure 3.** Plot of the rate constants  $k$  for the decay of  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{-TPP}$  represented as a function of the concentration of  $\text{CN-R}^1$ .

**TABLE 1: Rate Constants  $k_f$  and  $k_b$  and Equilibrium Constants  $K$  for the Formation of  $\text{Cl}(\text{CN-R}^n)\text{Cr}^{\text{III}}\text{-TPP}$  from  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{-TPP}$  in Toluene<sup>a</sup>**

	isocyanide

$k_f, \text{M}^{-1} \text{s}^{-1}$	$1.75 \times 10^7$	$1.7 \times 10^7$	$1.6 \times 10^7$	$1.6 \times 10^7$	$1.8 \times 10^7$
$k_b, \text{M}^{-1} \text{s}^{-1}$	$1.4 \times 10^5$	$1.6 \times 10^5$	$6 \times 10^5$	$1.9 \times 10^5$	$1.7 \times 10^5$
$K$	$1.25 \times 10^2$	$1.1 \times 10^2$	$2.7 \times 10$	$8.5 \times 10$	$1.1 \times 10$
$*k_f$ (calcd), $\text{M}^{-1} \text{s}^{-1}$	$2.9 \times 10^7$	$1.1 \times 10^7$	$1.8 \times 10^7$	$1.1 \times 10^7$	$1.7 \times 10^7$
$*k_b$ (calcd), $\text{M}^{-1} \text{s}^{-1}$	$2.3 \times 10^5$	$1.0 \times 10^5$	$6.6 \times 10^5$	$1.2 \times 10^5$	$1.6 \times 10^5$

<sup>a</sup> Experimental errors are within  $\pm 10\%$ .  $*k_f$  (calcd) and  $*k_b$  (calcd) are the values of  $k_f$  and  $k_b$  calculated with eqs 18 and 19.

order kinetics. The decay rate constant,  $k$ , was measured as a function of the concentration of  $\text{CN-R}^1$ . Figure 3 shows the plot of  $k$  vs  $[\text{CN-R}^1]$ , which gives a straight line with an intercept. According to eq 1, the rate constant  $k$  is expressed as

$$k = k_f[\text{CN-R}^1] + k_b[\text{H}_2\text{O}] \quad (4)$$

The slope and intercept of the line in Figure 3 give  $k_f = 1.75 \times 10^7 \text{ M}^{-1} \text{ s}^{-1}$  and  $k_b[\text{H}_2\text{O}] = 6.2 \times 10^2 \text{ s}^{-1}$ , respectively. From the latter value and  $[\text{H}_2\text{O}] = 4.4 \times 10^{-3} \text{ M}$ ,  $k_b$  is determined as  $1.40 \times 10^5 \text{ M}^{-1} \text{ s}^{-1}$ . The equilibrium constant  $K$  is calculated to be  $1.25 \times 10^2$ , in fairly good agreement with that obtained from the spectroscopic titration of  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{-TPP}$  with  $\text{CN-R}^1$ . In Table 1 are listed the values for  $k_f$ ,  $k_b$ , and  $K$  obtained with  $\text{CN-R}^n$ .

It is noteworthy that, in contrast to the case of chlorocobalt(III)<sup>12</sup> and -Fe(III) porphyrins,<sup>13</sup> the axial Cl of  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{-TPP}$  and  $\text{Cl}(\text{CN-R}^1)\text{Cr}^{\text{III}}\text{-TPP}$  is not photodissociated.

As mentioned above, the laser photolysis of  $\text{Cl}(\text{CN-R}^1)\text{Cr}^{\text{III}}\text{-TPP}$  in the toluene solution at 300 K yields short-lived species with a lifetime shorter than 1  $\mu\text{s}$ . To clearly detect the short-lived species, the laser photolysis of  $\text{Cl}(\text{CN-R}^1)\text{Cr}^{\text{III}}\text{-TPP}$  was carried out at the temperatures below 300 K. Figure 4 shows the transient spectra observed for the toluene solution of  $\text{Cl}(\text{CN-R}^1)\text{Cr}^{\text{III}}\text{-TPP}$  at 210 K after 355-nm laser pulsing. The transient spectrum detected at 50 ns has positive peaks at 442 and 498 nm and negative ones at 425 and 478 nm. At 2.5  $\mu\text{s}$  after pulsing, the fast decay component disappears, leaving the second transient spectrum, which has a positive peak at 442

**Figure 4.** Transient absorption spectra observed for the toluene solution of  $\text{Cl}(\text{CN-R}^1)\text{Cr}^{\text{III}}\text{-TPP}$  in the presence of  $1.13 \times 10^{-3} \text{ M CN-R}^1$  at 210 K. The spectra were taken at (a) 50 ns, (b) 2.5  $\mu\text{s}$ , and (c) 20  $\mu\text{s}$ .

nm and negative ones at 415 and 478 nm. The second transient further changes to the third one at ca. 20  $\mu\text{s}$  after pulsing. The third transient is readily ascribed to  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{-TPP}$  as observed by the laser photolysis of  $\text{Cl}(\text{CN-R}^1)\text{Cr}^{\text{III}}\text{-TPP}$  at 300 K. The second transient, which is a precursor of  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{-TPP}$ , is considered to be the five-coordinate  $\text{ClCr}^{\text{III}}\text{-TPP}$ . The transient spectrum taken at 50 ns after pulsing is interpreted as a sum of those of  $\text{Cl}(\text{CN-R}^1)\text{Cr}^{\text{III}}\text{-TPP}$  in the excited sextet state  ${}^6\text{T}_1$  and the five-coordinate  $\text{ClCr}^{\text{III}}\text{-TPP}$ . The sextet state of  $\text{Cl}(\text{CN-R}^1)\text{Cr}^{\text{III}}\text{-TPP}$  exhibits a positive peak around 500 nm<sup>4-7</sup> with a decay rate constant of  $1.6 \times 10^6 \text{ s}^{-1}$  at 210 K. The photochemistry of  $\text{Cl}(\text{CN-R}^1)\text{Cr}^{\text{III}}\text{-TPP}$  in the toluene solution is summarized as

$\text{Cl}(\text{CN-R}^1)\text{Cr}^{\text{III}}\text{-TPP}$  absorbs laser pulses to give the  ${}^6\text{T}_1$  state and the five-coordinate  $\text{ClCr}^{\text{III}}\text{-TPP}$ . The  ${}^6\text{T}_1$  state returns to the ground  $\text{Cl}(\text{CN-R}^1)\text{Cr}^{\text{III}}\text{-TPP}$ . The five-coordinate  $\text{ClCr}^{\text{III}}\text{-TPP}$  reacts with  $\text{H}_2\text{O}$  and  $\text{CN-R}^1$  to yield  $\text{Cl}(\text{CN-R}^1)\text{Cr}^{\text{III}}\text{-TPP}$  and  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{-TPP}$ , respectively.  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{-TPP}$  finally returns to  $\text{Cl}(\text{CN-R}^1)\text{Cr}^{\text{III}}\text{-TPP}$  according to eq 1. The results mentioned above leads to the conclusions that (1) the short-lived species detected at 300 K are ascribed to the  ${}^6\text{T}_1$  state of  $\text{Cl}(\text{CN-R}^1)\text{Cr}^{\text{III}}\text{-TPP}$  and (2) the long-lived transient  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{-TPP}$  observed at 300 K is produced by the reaction of the five-coordinate  $\text{ClCr}^{\text{III}}\text{-TPP}$  and  $\text{H}_2\text{O}$ .

Equations 8 and 9 are the competitive processes, and thus, the yield of  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{-TPP}$  is expected to diminish with the increase in the concentration of  $\text{CN-R}^1$ . The relative yields  $\Gamma$  for the formation of  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{-TPP}$  at 300 K are obtained by measuring the 448-nm absorbance change  $\Delta D(448 \text{ nm})$  at 1  $\mu\text{s}$  after laser pulsing. Figure 5 shows the plot of  $\Delta D(448 \text{ nm})$  vs

Figure 5. Plot of  $\Delta D(448 \text{ nm})$  as a function of  $[\text{CN-R}^1]$  (see text).

$[\text{CN-R}^1]$ . According to eqs 8 and 9,  $\Gamma$  is formulated as

$$\Gamma = \frac{\Delta D(448 \text{ nm})}{\Delta D_0(448 \text{ nm})} = \frac{k_{(\text{H}_2\text{O})}[\text{H}_2\text{O}]}{k_{(\text{H}_2\text{O})}[\text{H}_2\text{O}] + k_{(\text{CN-R}^1)}[\text{CN-R}^1]} \quad (10)$$

where  $\Delta D_0(448 \text{ nm})$  is the absorbance change at  $[\text{CN-R}^1] = 0$ . The plot of  $\Gamma^{-1}$  vs  $[\text{CN-R}^1]$  gives a straight line. From the slope of the line, the value of  $k_{(\text{CN-R}^1)}/(k_{(\text{H}_2\text{O})}[\text{H}_2\text{O}])$  at 300 K is obtained as  $8.33 \times 10 \text{ M}^{-1}$ , and thus,  $k_{(\text{CN-R}^1)}/k_{(\text{H}_2\text{O})} = 0.366$  at 300 K. Since  $k_{(\text{H}_2\text{O})}$  has been determined to be  $1.2 \times 10^9 \text{ M}^{-1}\text{s}^{-1}$ ,<sup>6</sup>  $k_{(\text{CN-R}^1)}$  at 300 K is obtained as  $4.4 \times 10^8 \text{ M}^{-1}\text{s}^{-1}$ .

**Mechanism of Ligand Substitution.** The ligand substitution reaction of coordination compounds is generally interpreted in terms of the  $\text{S}_{\text{N}}1$  or the  $\text{S}_{\text{N}}2$  type mechanism. On the assumption that the forward and backward reactions in eq 1 occur according to the  $\text{S}_{\text{N}}1$  type mechanism, the equilibrium between  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  and  $\text{Cl}(\text{CN-R}^1)\text{Cr}^{\text{III}}\text{TPP}$  is expressed by

Equations 11 and 12 lead to the following equation:

$$K = \frac{[\text{Cl}(\text{CN-R}^1)\text{Cr}^{\text{III}}\text{TPP}][\text{H}_2\text{O}]}{[\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}][\text{CN-R}^1]} = \frac{k_{(\text{CN-R}^1)} k_{\text{b}(\text{H}_2\text{O})}}{k_{\text{b}(\text{CN-R}^1)} k_{(\text{H}_2\text{O})}} \quad (13)$$

With the use of  $K = 1.25 \times 10^2$ ,  $k_{\text{b}(\text{H}_2\text{O})} = 3.5 \times 10^5 \text{ s}^{-1}$ ,<sup>6</sup>  $k_{(\text{H}_2\text{O})} = 1.2 \times 10^9 \text{ M}^{-1} \text{ s}^{-1}$ ,<sup>6</sup> and  $k_{(\text{CN-R}^1)} = 4.4 \times 10^8 \text{ M}^{-1} \text{ s}^{-1}$ , we obtain  $k_{\text{b}(\text{CN-R}^1)} = 1.0 \times 10^3 \text{ s}^{-1}$ . The equilibrium constant,  $K_{(\text{CN-R}^1)} = k_{(\text{CN-R}^1)}/k_{\text{b}(\text{CN-R}^1)}$ , in eq 12 is obtained as  $4.4 \times 10^5$ . In Table 2 are listed the values  $k_{(\text{CN-R}^n)}$ ,  $k_{\text{b}(\text{CN-R}^n)}$ , and the equilibrium constant  $K_{(\text{CN-R}^n)}$  for all  $\text{CN-R}^n$  studied.

From eqs 11 and 12, the rate constant  $k$  for achieving the equilibrium reaction (eq 1) can be obtained with the use of the

TABLE 2: Rate Constants  $k_{(\text{CN-R}^n)}$  and  $k_{\text{b}(\text{CN-R}^n)}$  and the Equilibrium Constants  $K_{(\text{CN-R}^n)}$  for the Formation of  $\text{Cl}(\text{CN-R}^n)\text{Cr}^{\text{III}}\text{TPP}$  from  $\text{ClCr}^{\text{III}}\text{TPP}$ , and the Quantum Yields  $\Phi$  for the Photodissociation of  $\text{CN-R}^n$  from  $\text{Cl}(\text{CN-R}^n)\text{Cr}^{\text{III}}\text{TPP}$ <sup>a</sup>

steady-state approximation with regard to  $\text{ClCr}^{\text{III}}\text{TPP}$ :

$$d[\text{ClCr}^{\text{III}}\text{TPP}]/dt = 0 \quad (14)$$

$$[\text{ClCr}^{\text{III}}\text{TPP}] \ll [\text{Cl}(\text{CN-R}^1)\text{Cr}^{\text{III}}\text{TPP}] \text{ and } [\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}] \quad (15)$$

Equations 11, 12, 14, and 15 give the expression for  $k$  as follows.

$$k = \frac{k_{\text{b}(\text{H}_2\text{O})}k_{(\text{CN-R}^1)}[\text{CN-R}^1] + k_{(\text{H}_2\text{O})}k_{\text{b}(\text{CN-R}^1)}[\text{H}_2\text{O}]}{k_{(\text{H}_2\text{O})}[\text{H}_2\text{O}] + k_{(\text{CN-R}^1)}[\text{CN-R}^1]} \quad (16)$$

Since  $k_{(\text{H}_2\text{O})}[\text{H}_2\text{O}] \gg k_{(\text{CN-R}^1)}[\text{CN-R}^1]$  holds in the present system ( $[\text{CN-R}^1] < 10^{-3} \text{ M}$ ), eq 16 is transformed to eq 17:

$$k = \{k_{\text{b}(\text{H}_2\text{O})}k_{(\text{CN-R}^1)}[\text{CN-R}^1]\} \{k_{(\text{H}_2\text{O})}[\text{H}_2\text{O}]\}^{-1} + k_{\text{b}(\text{CN-R}^1)} \quad (17)$$

From eqs 4 and 17,  $k_f$  and  $k_b$  are, respectively, represented as

$$k_f = \{k_{\text{b}(\text{H}_2\text{O})}k_{(\text{CN-R}^1)}\} \{k_{(\text{H}_2\text{O})}[\text{H}_2\text{O}]\}^{-1} \quad (18)$$

$$k_b = k_{\text{b}(\text{CN-R}^1)}[\text{H}_2\text{O}]^{-1} \quad (19)$$

Thus, when the equilibrium reaction in eq 1 proceeds via an intermediate  $\text{ClCr}^{\text{III}}\text{TPP}$ ,  $k_f$  and  $k_b$  will be given by eqs 18 and 19, respectively. In Table 1 are listed the  $^*k_f$  and  $^*k_b$  values, which are calculated for  $\text{CN-R}^n$  according to eqs 18 and 19 with the use of  $k_{\text{b}(\text{H}_2\text{O})}$ ,  $k_{(\text{H}_2\text{O})}$ ,  $k_{(\text{CN-R}^1)}$ ,  $k_{\text{b}(\text{CN-R}^1)}$ , and  $[\text{H}_2\text{O}]$ . It is found from Table 1 that the values of  $k_f$  and  $k_b$  experimentally obtained are moderately in good agreement with those of  $^*k_f$  and  $^*k_b$  calculated. This finding suggests that the ligand-substitution reaction in eq 1 occurs through the  $\text{S}_{\text{N}}1$ -type mechanism; i.e., the five-coordinate  $\text{ClCr}^{\text{III}}\text{TPP}$  is a key intermediate in eq 1.

**Temperature Dependence of Rate Constants.** From eqs 8 and 9, the rate constant  $k_d(T)$  for the decay of  $\text{ClCr}^{\text{III}}\text{TPP}$  at a temperature  $T$  is given by

$$k_d(T) = k_{(\text{CN-R}^1)}(T)[\text{CN-R}^1] + k_{(\text{H}_2\text{O})}(T)[\text{H}_2\text{O}] \quad (20)$$

The value of  $k_d(T)$  was measured in the temperature range 200–300 K.  $k_d(T)$  was found to decrease with a decrease in temperature. Thus, the associations of  $\text{CN-R}^1$  and  $\text{H}_2\text{O}$  to  $\text{ClCr}^{\text{III}}\text{TPP}$  are expected to be activation processes. The two terms  $k_{(\text{CN-R}^1)}(T)$  and  $k_{(\text{H}_2\text{O})}(T)$  in eq 20 at various temperatures are separately obtained by measuring both  $k_d(T)$  and the relative

**Figure 6.** Plots of the absorbance changes  $\Delta D_0(448 \text{ nm}, T)$  (○) and  $\Delta D_0(433 \text{ nm}, T)$  (●) as a function of temperature.

quantum yields for the photochemical formation of  $\text{ClCr}^{\text{III}}\text{TPP}$  and  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  from  $\text{Cl}(\text{CN}-\text{R}^1)\text{Cr}^{\text{III}}\text{TPP}$  in the toluene solution as a function of  $T$ .

Figure 6 shows the plots of  $\Delta D_0(448 \text{ nm}, T)$  and  $\Delta D_0(433 \text{ nm}, T)$  observed at a temperature  $T$  for a toluene solution of  $\text{Cl}(\text{CN}-\text{R}^1)\text{Cr}^{\text{III}}\text{TPP}$  in the presence of  $1.13 \times 10^{-3} \text{ M}$   $\text{CN}-\text{R}^1$ , represented as a function of temperature. Here,  $\Delta D_0(433 \text{ nm}, T)$  was measured at 433 nm immediately after the  ${}^6\text{T}_1$  state of  $\text{Cl}(\text{CN}-\text{R}^1)\text{Cr}^{\text{III}}\text{TPP}$  disappeared. The values of  $\Delta D_0(448 \text{ nm}, T)$  and  $\Delta D_0(433 \text{ nm}, T)$  are, respectively, the relative yields for the formation of  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  and  $\text{ClCr}^{\text{III}}\text{TPP}$ . As shown in Figure 6,  $\Delta D_0(433 \text{ nm}, T)$  is  $0.18 \pm 0.1$  in the temperature range 200–300 K. Therefore, the quantum yield for the photodissociation of  $\text{CN}-\text{R}^1$  from  $\text{Cl}(\text{CN}-\text{R}^1)\text{Cr}^{\text{III}}\text{TPP}$  is concluded to be independent of temperature in the range studied. However,  $\Delta D_0(448 \text{ nm}, T)$  shows a temperature dependence: the yield for the formation of  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  increases with an increase in temperature and levels off above 260 K to give a value of  $\Delta D_0(448 \text{ nm}, \infty) = 0.35$ . These results indicate that the observed low yields of  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  at low temperatures are ascribed to the decrease in  $k_{(\text{H}_2\text{O})}(T)$ . On the basis of the results mentioned above and eqs 8 and 9, the relative yield  $\phi_r(T)$  for the formation of  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  is represented as

$$\phi_r(T) = \Delta D_0(448 \text{ nm}, T) / \Delta D_0(448 \text{ nm}, 300 \text{ K})$$

$$= (\Gamma)^{-1} k_{(\text{H}_2\text{O})}(T) [\text{H}_2\text{O}] \{ k_{(\text{CN}-\text{R}^1)}(T) [\text{CN}-\text{R}^1] + k_{(\text{H}_2\text{O})}(T) [\text{H}_2\text{O}] \}^{-1} \quad (21)$$

Here,  $\phi_r(T) = 1.0$  at 300 K, and thus, the  $\Gamma$  value in the present system ( $[\text{CN}-\text{R}^1] = 1.13 \times 10^{-3} \text{ M}$  and  $[\text{H}_2\text{O}] = 4.4 \times 10^{-3} \text{ M}$ ) is calculated to be 0.91 from eq 10. Equations 20 and 21 lead to

$$k_{(\text{H}_2\text{O})}(T) = k_d(T) \Gamma \phi_r(T) / [\text{H}_2\text{O}] \quad (22)$$

$$k_{(\text{CN}-\text{R}^1)}(T) = k_d(T) \{1 - \Gamma \phi_r(T)\} / [\text{CN}-\text{R}^1] \quad (23)$$

By use of  $[\text{H}_2\text{O}] = 4.4 \times 10^{-3} \text{ M}$ ,  $[\text{CN}-\text{R}^1] = 1.13 \times 10^{-3} \text{ M}$ ,  $k_d(T)$ , and  $\phi_r(T)$ , the values of  $k_{(\text{H}_2\text{O})}(T)$  and  $k_{(\text{CN}-\text{R}^1)}(T)$  are obtained at various temperatures.

Figure 7 shows  $k_{(\text{H}_2\text{O})}(T)$  and  $k_{(\text{CN}-\text{R}^1)}(T)$  represented as a function of temperature. The plots of  $\log k_{(\text{H}_2\text{O})}(T)$  and  $\log k_{(\text{CN}-\text{R}^1)}(T)$  vs  $1/T$  gave straight lines. The Arrhenius expressions for  $k_{(\text{H}_2\text{O})}(T)$  and  $k_{(\text{CN}-\text{R}^1)}(T)$  are

$$k_{(\text{H}_2\text{O})}(T) = 1.7 \times 10^{14} \exp\left(-\frac{7.0 \times 10^3}{RT}\right) \text{M}^{-1} \text{s}^{-1} \quad (24)$$

**Figure 7.** Rate constants  $k_{(\text{H}_2\text{O})}(T)$  (○) and  $k_{(\text{CN}-\text{R}^1)}(T)$  (●) as a function of temperature.

$$k_{(\text{CN}-\text{R}^1)}(T) = 4.0 \times 10^{11} \exp\left(-\frac{4.1 \times 10^3}{RT}\right) \text{M}^{-1} \text{s}^{-1} \quad (25)$$

The relative yield for the formation of the  ${}^6\text{T}_1$  state of  $\text{Cl}(\text{CN}-\text{R}^1)\text{Cr}^{\text{III}}\text{TPP}$  was measured in the temperature range 180–300 K by monitoring the absorbance change at 500 nm after laser pulsing. The yield exhibited a slight increase below 190 K.

**Quantum-Yield Measurements.** Quantum yields  $\Phi$  for the formation of  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  from  $\text{Cl}(\text{CN}-\text{R}^1)\text{Cr}^{\text{III}}\text{TPP}$  were measured at room temperature by the laser-photolysis method described earlier.<sup>14</sup> The absorbance change  $\Delta D_0(448 \text{ nm})$  is shown by

$$\Delta D_0(448 \text{ nm}) = I_{\text{abs}} \Delta \epsilon_{\text{AB}} \Phi / N_A \quad (26)$$

Here,  $I_{\text{abs}}$  is the number of 355-nm photons absorbed by a toluene solution of  $\text{Cl}(\text{CN}-\text{R}^1)\text{Cr}^{\text{III}}\text{TPP}$  upon laser photolysis,  $\Delta \epsilon_{\text{AB}}$  is the difference in the molar absorption coefficients at 448 nm between  $\text{Cl}(\text{CN}-\text{R}^1)\text{Cr}^{\text{III}}\text{TPP}$  and  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$ , and  $N_A$  is the Avogadro number. For determination of  $I_{\text{abs}}$ , a benzene solution of benzophenone, which is prepared to have the same absorbance at 355 nm as that of the toluene solution of  $\text{Cl}(\text{CN}-\text{R}^1)\text{Cr}^{\text{III}}\text{TPP}$ , was used; the molar absorption coefficient  $\epsilon_T$  and the yield  $\Phi_T$  of the triplet benzophenone have already been determined as  $7.8 \times 10^3 \text{ M}^{-1} \text{ cm}^{-1}$  at 530 nm and 1.0, respectively.<sup>15,16</sup> The absorbance of the triplet benzophenone,  $\Delta D_T(530 \text{ nm})$  observed after 355-nm laser pulsing, is expressed as

$$\Delta D_T(530 \text{ nm}) = I_{\text{abs}} \epsilon_T \Phi_T / N_A \quad (27)$$

From eqs 26 and 27, eq 28 is derived:

$$\Phi = \Phi_T \frac{\epsilon_T}{\Delta \epsilon_{\text{AB}}} \frac{\Delta D_0(448 \text{ nm})}{\Delta D_T(530 \text{ nm})} \quad (28)$$

The quantum yield for the formation of  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  by laser photolysis of  $\text{Cl}(\text{CN}-\text{R}^1)\text{Cr}^{\text{III}}\text{TPP}$  in toluene containing  $1.13 \times 10^{-3} \text{ M}$   $\text{CN}-\text{R}^1$  and  $4.4 \times 10^{-3} \text{ M}$   $\text{H}_2\text{O}$  is obtained as 0.086 at 300 K. As mentioned above,  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  is produced by the reaction of  $\text{ClCr}^{\text{III}}\text{TPP}$  with  $\text{H}_2\text{O}$  in toluene. Thus, the yield  $\Phi(\text{ClCr}^{\text{III}}\text{TPP})$  for the formation of  $\text{ClCr}^{\text{III}}\text{TPP}$  is represented by

$$\Phi(\text{ClCr}^{\text{III}}\text{TPP}) = \Phi \frac{k_{(\text{CN}-\text{R}^1)}[\text{CN}-\text{R}^1] + k_{(\text{H}_2\text{O})}[\text{H}_2\text{O}]}{k_{(\text{H}_2\text{O})}[\text{H}_2\text{O}]} \quad (29)$$

The value of  $\Phi(\text{ClCr}^{\text{III}}\text{TPP})$  at 300 K is determined as 0.094

## SCHEME 1

from eq 29. In Table 2 are listed the quantum yields for the formation of  $\text{ClCr}^{\text{III}}\text{TPP}$  from five isocyanide complexes of  $\text{ClCr}^{\text{III}}\text{TPP}$  in toluene at 300 K.

## Discussion

A number of isocyanide complexes have been synthesized and characterized in order to elucidate the nature of the bonding between metal and isocyanides.<sup>17</sup> For metalloporphyrins, isocyanide complexes of iron<sup>18–21</sup> and rhodium porphyrins<sup>22,23</sup> have been well studied; the crystallographic structures of these complex are the bis[isocyanide] complexes.<sup>19,20,22</sup> The present study revealed that chromium(III) tetraphenylporphyrin forms a 1:1 complex with isocyanide in toluene solutions.

The equilibrium constants for the formation of  $\text{Cl}(\text{CN}-\text{R}^n)\text{Cr}^{\text{III}}\text{TPP}$  from  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  are found to be ranged from 10 to  $10^2$ .

The laser-photolysis studies of  $\text{Cl}(\text{CN}-\text{R}^1)\text{Cr}^{\text{III}}\text{TPP}$  in the toluene solution containing  $4.4 \times 10^{-3}$  M  $\text{H}_2\text{O}$  demonstrate that the axial  $\text{CN}-\text{R}^1$  is photodissociated to give five-coordinate  $\text{ClCr}^{\text{III}}\text{TPP}$ , which reacts with both  $\text{H}_2\text{O}$  and  $\text{CN}-\text{R}^1$  to yield  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  and  $\text{Cl}(\text{CN}-\text{R}^1)\text{Cr}^{\text{III}}\text{TPP}$ , respectively. The detection of  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  as a transient indicates that the rate for the association of  $\text{H}_2\text{O}$  to  $\text{ClCr}^{\text{III}}\text{TPP}$  is faster than that of  $\text{CN}-\text{R}^1$  in this solution at 300 K. The transient  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  further reacts with  $\text{CN}-\text{R}^1$  to regenerate  $\text{Cl}(\text{CN}-\text{R}^1)\text{Cr}^{\text{III}}\text{TPP}$ . The rate constant for association of  $\text{H}_2\text{O}$  to  $\text{ClCr}^{\text{III}}\text{TPP}$  has been determined as  $1.2 \times 10^9 \text{ M}^{-1} \text{ s}^{-1}$ ,<sup>6</sup> and those of  $\text{CN}-\text{R}^n$  are  $(1.7-5.3) \times 10^8 \text{ M}^{-1} \text{ s}^{-1}$ .

$\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  and  $\text{Cl}(\text{CN}-\text{R}^n)\text{Cr}^{\text{III}}\text{TPP}$  are in equilibrium in the toluene solution containing  $\text{CN}-\text{R}^n$ . The equilibrium constant  $K$  depends on the nature of  $\text{CN}-\text{R}^n$ . According to the laser-photolysis studies, the transient product  $\text{ClCr}^{\text{III}}\text{TPP}$  initially attains the equilibria shown by eqs 11 and 12. Since the rates for the dissociation of  $\text{H}_2\text{O}$  and  $\text{CN}-\text{R}^n$  in eqs 11 and 12 are very slow,  $\text{ClCr}^{\text{III}}\text{TPP}$  disappears to generates either  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  or  $\text{Cl}(\text{CN}-\text{R}^n)\text{Cr}^{\text{III}}\text{TPP}$ . Then  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  relaxes toward the equilibrium given by eq 1. The forward rate constants in eq 1 are almost identical:  $(1.6-1.8) \times 10^7 \text{ M}^{-1} \text{ s}^{-1}$  for all isocyanide complexes used. However, the backward rate constants in eq 1 vary from  $10^5$  to  $10^6 \text{ M}^{-1} \text{ s}^{-1}$ .

The ligand-substitution reactions of  $\text{Cl}(\text{L})\text{Cr}^{\text{III}}\text{TPP}$  (L: axial ligand) have been interpreted on the assumption that the reactions proceed via a five-coordinate intermediate  $\text{ClCr}^{\text{III}}\text{TPP}$ .<sup>4,6</sup> The detailed kinetic analysis of the present system also suggests that  $\text{ClCr}^{\text{III}}\text{TPP}$  is a key intermediate in eq 1. The reaction mechanism of the present system is displayed in Scheme 1.

The rate constants for the association of  $\text{H}_2\text{O}$  and  $\text{CN}-\text{R}^1$  toward  $\text{ClCr}^{\text{III}}\text{TPP}$  were measured by laser photolysis of the toluene solution of  $\text{Cl}(\text{CN}-\text{R}^1)\text{Cr}^{\text{III}}\text{TPP}$  in the temperature range 300–200 K. The activation energy and preexponential factor obtained for the association of  $\text{H}_2\text{O}$  toward  $\text{ClCr}^{\text{III}}\text{TPP}$  are markedly larger than those expected from the diffusion process; the former is  $1.7 \times 10^{14} \text{ M}^{-1} \text{ s}^{-1}$  and the latter 7 kcal mol<sup>-1</sup>. In an earlier paper, we have studied the photochemistry of  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  in a polystyrene film. The laser photolysis of  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  in the film results in the dissociation of the axial  $\text{H}_2\text{O}$  to produce  $\text{ClCr}^{\text{III}}\text{TPP}$ . The bimolecular rate constant for the recombination reaction between  $\text{H}_2\text{O}$  and  $\text{ClCr}^{\text{III}}\text{TPP}$  measured in the temperature range 200–300 K gives a preexponential factor of  $10^{15} \text{ M}^{-1} \text{ s}^{-1}$  and an activation energy of 7 kcal mol<sup>-1</sup>. Fairly large preexponential factors obtained for toluene solutions and polystyrene films suggest that water molecules in a hydrophobic solvent are able to move around more quickly than in a diffusion process. The activation energy obtained with toluene solutions is close to that with polystyrene films. Probably the reaction between  $\text{ClCr}^{\text{III}}\text{TPP}$  and  $\text{H}_2\text{O}$  in toluene proceeds via the same activation complex as that in polystyrene film. The frequency factor and activation energy obtained with the reaction of  $\text{ClCr}^{\text{III}}\text{TPP}$  and  $\text{CN}-\text{R}^1$  can be explained by assuming the diffusion process.

The quantum yields for formation of  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  from  $\text{Cl}(\text{CN}-\text{R}^n)\text{Cr}^{\text{III}}\text{TPP}$  in toluene containing  $4.4 \times 10^{-3}$  M water and ca.  $10^{-3}$  M  $\text{CN}-\text{R}^n$  are determined as ca. 0.1 at 300 K. Since  $\text{ClCr}^{\text{III}}\text{TPP}$  produced from photolysis of  $(\text{CN}-\text{R}^n)\text{Cr}^{\text{III}}\text{TPP}$  mostly reacts with  $\text{H}_2\text{O}$  to produce  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  in the toluene solutions, the yields for photodissociation of  $\text{CN}-\text{R}^n$  from the isocyanide complexes are calculated as ca. 0.1. These values are smaller than those of the photodissociation yields of the axial ligands from other six-coordinate chlorochromium(III) porphyrins.<sup>4,6</sup>

Photoinduced dissociation of axial ligands have been investigated for  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$ ,<sup>6,7</sup>  $\text{Cl}(\text{Py})\text{Cr}^{\text{III}}\text{TPP}$ ,<sup>6,7</sup>  $\text{Cl}(\text{CH}_3\text{-COCH}_3)\text{Cr}^{\text{III}}\text{TPP}$ ,<sup>4</sup> and  $\text{ONO}-\text{Cr}^{\text{III}}\text{TPP}$ .<sup>5</sup> The reactions are found to occur from the <sup>4</sup>S<sub>1</sub> state. The long-lived excited state <sup>6</sup>T<sub>1</sub> is not responsible for photodissociation of the axial ligands.<sup>4–7</sup> The laser photolysis of  $\text{Cl}(\text{CN}-\text{R}^1)\text{Cr}^{\text{III}}\text{TPP}$  in toluene also gives rise to the formation of the <sup>6</sup>T<sub>1</sub> state. The lifetimes  $\tau$  of the <sup>6</sup>T<sub>1</sub> state are 280 ns in degassed toluene and  $\tau < 70$  ns in oxygen-saturated toluene at 1 atm. It is clear that the <sup>6</sup>T<sub>1</sub> state is quenched by oxygen. However, the yield for the formation of  $\text{ClCr}^{\text{III}}\text{TPP}$  and  $\text{Cl}(\text{H}_2\text{O})\text{Cr}^{\text{III}}\text{TPP}$  from  $\text{Cl}(\text{CN}-\text{R}^1)\text{Cr}^{\text{III}}\text{TPP}$  in the degassed solution is identical with that in the oxygen-saturated solution. This finding indicates that, like other chromium porphyrins,<sup>4–7</sup> the <sup>6</sup>T<sub>1</sub> state is not a reactive state, and the <sup>4</sup>S<sub>1</sub> state would be responsible for the photodissociation of  $\text{CN}-\text{R}^1$  from  $\text{Cl}(\text{CN}-\text{R}^n)\text{Cr}^{\text{III}}\text{TPP}$ . The quantum yield (ca. 0.1) for the photodissociation of  $\text{CN}-\text{R}^n$  from  $\text{Cl}(\text{CN}-\text{R}^n)\text{Cr}^{\text{III}}\text{TPP}$  is independent of temperature in the range 300–200 K. Thus, the dissociation of  $\text{CN}-\text{R}^1$  from the reactive excited state is concluded to occur without any activation energy in the temperature range 200–300 K.
