# Geometry and Electronic Structure of Titanacycloalkenes 

Daniel B. Lawson* and Roger L. DeKock<br>Department of Chemistry and Biochemistry, Calvin College, Grand Rapids, Michigan 49546

Received: August 25, 1998; In Final Form: December 30, 1998

#### Abstract

A number of titanacycloalkenes, $\mathrm{H}_{2} \mathrm{TiC}_{2} \mathrm{H}_{2}, \mathrm{HTiC}_{3} \mathrm{H}_{3}, \mathrm{H}_{2} \mathrm{TiC}_{4} \mathrm{H}_{4}$, and $\mathrm{HTiC}_{5} \mathrm{H}_{5}$, have been studied using ab initio techniques. Vibrational frequencies were computed at the RHF, MP2, BLYP, and B3LYP levels. Both a LANL2DZ pseudopotential and an all-electron TZV basis set was used for each method. The electronic structure of the systems of interest is characterized in terms of natural resonance theory (NRT) and the atoms in molecules (AIM) analysis. All rings are planar except for titanabenzene, $\mathrm{HTiC}_{5} \mathrm{H}_{5} . \mathrm{H}_{2} \mathrm{TiC}_{2} \mathrm{H}_{2}$ has $C_{2 v}$ symmetry and has single $\mathrm{Ti}-\mathrm{C}$ bonds. $\mathrm{HTiC}_{3} \mathrm{H}_{3}$, unlike the isovalent cyclobutadiene and silacyclobutadiene, has $C_{2 v}$ symmetry and shows significant electron delocalization. In $\mathrm{H}_{2} \mathrm{TiC}_{4} \mathrm{H}_{4}$ the $\mathrm{TiC}_{4}$ ring is planar with equivalent single $\mathrm{Ti}-\mathrm{C}$ bonds and has $C_{2 v}$ symmetry. $\mathrm{HTiC}_{5} \mathrm{H}_{5}$ has a boat-shaped geometry where the angle between the CTiC plane and the plane formed by the neighboring four carbon atoms is nearly $90^{\circ}$. AIM analysis isolates a weak critical point between Ti and the para-C atom, and NRT analysis confirms the weak bonding interaction.

## Introduction

Titanium finds its way into many organometallic compounds and thus offers a very practical transition metal to study. Like carbon, titanium has four valence electrons and the most common oxidation state is $\mathrm{Ti}(\mathrm{IV}) .{ }^{1}$ Similarities in the valence electron configuration provides similar characteristics in terms of bonding. For example, both $\mathrm{TiCl}_{4}$ and $\mathrm{CCl}_{4}$ have tetrahedral geometries. However, unlike carbon, titanium utilizes d orbitals in its bonding to other atoms. Furthermore, C and Ti differ in atomic orbital size, polarizability, and electronegativity. As a result, the carbon atom is not always prone to form double and triple bonds with Ti as it would with another C atom.

Understanding the carbon-titanium interaction is important in many industrial processes and compounds. Catalytic processes being one of the most common, e.g., the Ziegler-Natta alkene polymerization. ${ }^{1}$ In terms of cluster chemistry, carbon-titanium bonding has focused primarily on metallocarbohedrenes (metcars), such as those of Castleman and co-workers. ${ }^{2}$ Recently, however, experimental studies of small carbon titanium clusters, ${ }^{3}$ $\mathrm{TiC}_{x}(x=2-5)$, show these molecules to have a preference for forming rings similar to those of $\mathrm{YC}_{x}{ }^{4}$ and $\mathrm{LaC}_{x} .{ }^{5}$ The theoretically based investigation of $\mathrm{TiC}_{x}{ }^{6}$ clusters indicate that the $x=3$ and 4 structures are planar ring structures with singlet ground states. In that study bonding between Ti and C was determined to be primarily ionic. Little work has been done on aromatic hydrocarbons with titanium carbon substitution. Exploring the nature of the $\mathrm{Ti}-\mathrm{C}$ bond in unsaturated hydrocarbons would be of interest in expanding the understanding of both catalytic processes and met-cars chemistry.

We present here an ab initio study of a single Ti substitution for a C atom within a series of unsaturated cycloalkenes. Recently, $\mathrm{H}_{2} \mathrm{TiC}_{2} \mathrm{H}_{2}$ was isolated by Lee, Manceron, and Papái ${ }^{7}$ by co-deposition of ground-state Ti atoms and ethene molecules in excess argon at low temperature followed by selective electronic excitation of the Ti atoms. Their study concluded that the ground state of the molecule was a singlet. Furthermore, the theoretical studies of $\mathrm{TiC}_{3}$ and $\mathrm{TiC}_{4}$ indicate the ground state of these small molecules to be a singlet and to have a fan or
ring structure. ${ }^{6}$ In the systems presented here, the open valences of Ti and C are filled with hydrogen and, therefore, the four molecules characterized in this study are presumed to have singlet ground states with cyclic geometries. In the case of $\mathrm{HTiC}_{3} \mathrm{H}_{3}$, a system isovalent to cyclobutadiene and silacyclobutadiene, the triplet state is expected to be low-lying and the singlet-triplet splitting is determined. We attempt to characterize the bonding in these novel transition metal compounds, as well as to present the geometry and vibrational frequencies. We have not determined every possible isomer but presume our structures to be low-lying if not the true ground states.

## Calculation Details

Restricted Hartree-Fock (RHF) geometries were first obtained with the Los Alamos effective core potential plus double- $\zeta$ (LANL2DZ) of Hay and Wadt ${ }^{8}$ on Ti and an all-electron Dunning ${ }^{9} 9 \mathrm{~s} 5 \mathrm{p}$ (D95) basis with additional p and d functions ${ }^{10}$ on C and an additional p function ${ }^{10}$ on H . The combination of these functions will be referred to as the ECP. Correlation corrections to the RHF wave functions were included at the level of second-order Möller-Plesset perturbation (MP2). Energy calculations, analytic geometry optimizations, and analytic frequency calculations were also performed using density functional methods (DFT) with the correlation functional of Lee, Yang, and Parr ${ }^{11}$ in combination with Becke's 1988 exchange functional ${ }^{12}$ (BLYP) and Becke's three-parameter hybrid functional ${ }^{13}$ (B3LYP). In the instance of the triplet state of $\mathrm{HTiC}_{3} \mathrm{H}_{3}$, all calculations were performed with restricted open-shell Hartree-Fock (ROHF), restricted open-shell MöllerPlesset perturbation (ROMP2), restricted open-shell BLYP (ROBLYP), and restricted open-shell B3LYP (ROB3LYP). All electron basis calculations were performed following the LANL2DZ calculations with a TZV basis on Ti as given in ref 15 c of Glezakou and Gordon ${ }^{14}$ and a $\mathrm{TZV}^{15}$ basis on C and H . The Ti TZV basis is a Watcher's ${ }^{16}$ basis (14s9p5d) extended to triple- $\zeta$ quality. Diffuse s, p, and d polarization functions were included as given in Glezakou and Gordon. ${ }^{14}$ All calculations were performed with the Gaussian94 package. ${ }^{17}$ Geometries

were optimized without symmetry, and frequencies were computed with the highest level symmetry available. Natural resonance theory (NRT) resonance structures and bond orders were acquired from NBO 4.0. ${ }^{18}$ Calculations were carried out on PC computers running Linux with some of the larger calculations being performed on an IBM RS/6000 workstation.

## Results

The RHF and MP2 wave functions of titanacyclopropene, $\mathrm{H}_{2} \mathrm{TiC}_{2} \mathrm{H}_{2}$, have an energy-optimized molecular symmetry of $C_{2 v}$ with the CTiC atoms lying in a plane along with the $\mathrm{C}-\mathrm{H}$ bonds as shown in Figure 1A. The two $\mathrm{H}-\mathrm{Ti}$ bonds lie above and below the CTiC plane with the HTiH plane perpendicular to the $\mathrm{C}-\mathrm{C}$ bond. The B3LYP functional also gives $C_{2 v}$ molecular symmetry, however, only with the TZV basis. Both BLYP and B3LYP functionals give the molecular symmetry of $C_{s}$ with the ECP basis; the BLYP functional gives $C_{s}$ symmetry with the TZV basis. In these lower symmetry geometries the HTiH plane forms an angle with the $\mathrm{C}-\mathrm{C}$ bond of $129.8^{\circ}, 123.2^{\circ}$, and $162.2^{\circ}$ for the B3LYP/ECP, the BLYP/ ECP, and the BLYP/TZV, respectively. Upon inclusion of $f$ basis functions ${ }^{19}$ to the TZV basis, the BLYP functional optimized the molecular geometry to $C_{2 v}$ symmetry. The energy to optimize from the $C_{s} \mathrm{BLYP} / \mathrm{TZV}$ geometry to the energyoptimized BLYP/TZV+2f $C_{2 v}$ geometry is $1.1 \mathrm{kcal} / \mathrm{mol}$, reflecting the shallow nature of the HTiH wagging potential. ECP and all-electron TZV bond lengths and bond angles for the various techniques are summarized in Table 1. The $\mathrm{Ti}-\mathrm{C}$ bond length varies by less than $0.01 \AA$ for each method, whereas the $\mathrm{C}-\mathrm{C}$ bond length varies by $0.05 \AA$. This implies a greater sensitivity of the $\mathrm{C}-\mathrm{C}$ bond to methodology than for the $\mathrm{Ti}-\mathrm{C}$ bonds. The ECP bond lengths are very similar to the all-electron TZV basis with the largest difference in the $\mathrm{Ti}-\mathrm{C}$ bond length being $0.04 \AA$ greater for MP2/ECP than the MP2/TZV, the largest difference in the $\mathrm{C}-\mathrm{C}$ bond length being $0.03 \AA$ less

Figure 1. Ground-state B3LYP/TZV geometries of the titanacycloalkenes.
for MP2/ECP than the MP2/TZV, and less than $0.01 \AA$ on the $\mathrm{C}-\mathrm{H}$ bond lengths for all methods. Greater discrepancies were found for the $\mathrm{Ti}-\mathrm{H}$ bond lengths with the greatest increase of $0.07 \AA$ from the MP2/ECP to the MP2/TZV.

As mentioned in the Introduction, this molecule has been observed in a recent matrix isolation experiment. ${ }^{7}$ The authors reported vibrational frequencies and results of DFT calculations. Table 2 provides the vibrational frequencies of our work along with the BLYP and experimental results of the reference work. Our theoretical vibrational frequencies compare well with both the experimental frequencies and those calculated in the

|  |  | 0.75 | 0.23 | 0.98 |

reference work with the exception of the HTiH wag. In the work of Lee et al., the BLYP and BP86 methods optimize the molecular geometry to $C_{s}$ symmetry. They reasoned that a shallow HTiH wagging potential and the low HTiH experimental vibrational frequency indicated that the molecule was better modeled by BP86 and BLYP functionals in $C_{s}$ symmetry. However, with additional f basis functions, the nonhybrid method of BLYP gives an even lower HTiH wagging vibrational frequency than does B3LYP in the $C_{2 v}$ symmetry. The experimental value for the HTiH wag was assigned as $277 \mathrm{~cm}^{-1}$. RHF/ TZV and MP2/TZV results give this same frequency at 314 and $206 \mathrm{~cm}^{-1}$, respectively, whereas B3LYP/TZV and BLYP/ TZV +2 f give lower values of 145 and $22 \mathrm{~cm}^{-1}$. The overall average of the differences between all of the computed and the experimental frequencies is $76 \mathrm{~cm}^{-1}$ for RHF/TZV, $56 \mathrm{~cm}^{-1}$ for MP2/TZV, $51 \mathrm{~cm}^{-1}$ for B3LYP/TZV, and $47 \mathrm{~cm}^{-1}$ for BLYP/TZV+2f. The average differences are reduced for the B3LYP and BLYP by 9 and $23 \mathrm{~cm}^{-1}$ if the HTiH wagging frequency is neglected.

Several methods are available for evaluating wave functions. This paper reports the results of two methods, natural resonance theory (NRT) ${ }^{20}$ and atoms in molecules (AIM). ${ }^{21}$ NRT provides a method of interpreting the one-particle density matrix in terms of chemical resonance structures and their percentage contribution to the molecular density; bond orders and significant resonance structures are provided in Table 3 and Figure 2. NRT indicates that the $\mathrm{Ti}-\mathrm{C}$ bonds and the $\mathrm{Ti}-\mathrm{H}$ bonds are quite ionic. This is not surprising considering the electronegativity of Ti is considerably less than either carbon or hydrogen. The B3LYP Mulliken charges are $+0.70 e,-0.36 e$, and $-0.19 e$ on $\mathrm{Ti}, \mathrm{C}$, and the Ti-bound H , respectively. The total $\mathrm{C}-\mathrm{C}$ and $\mathrm{Ti}-\mathrm{C}$ bond orders are 1.97 and 0.97 , respectively. The primary resonance structure shows a contribution of $76.7 \%$ and corresponds to a double $\mathrm{C}-\mathrm{C}$ bond and single $\mathrm{Ti}-\mathrm{C}, \mathrm{Ti}-\mathrm{H}$, and $\mathrm{C}-\mathrm{H}$ bonds. A "nonbonded" structure contributes $6.9 \%$; all other NRT resonance structures have contributions below $2 \%$ and are neglected. Bond strain has been reported in similar systems such as the silatitanacyclobutanes. ${ }^{14}$ Bader's AIM analysis is used to locate critical points and to evaluate bond strain in the ring. The critical points are locations where the gradient of the density is zero and therefore allow the identification of bond paths and rings. Figure 3 shows critical points and

$5.9 \%$

Figure 2. NRT resonance structures and percentage contributions.

Figure 3. Critical points of $\mathrm{H}_{2} \mathrm{TiC}_{2} \mathrm{H}_{2}$ marked by an "*" and the ring point marked by an open circle.
the ring point for the B3LYP/TZV density of $\mathrm{H}_{2} \mathrm{TiC}_{2} \mathrm{H}_{2}$. Considerable bond strain occurs between the $\mathrm{Ti}-\mathrm{C}$ bonds, whereas critical points lie directly on the lines between the other bonded atoms.

To the authors' knowledge, no experimental or theoretical data is available for the remaining three molecules. In considering the systems presented here, two molecules have one H bound to the Ti center and two have two H atoms bound to Ti. It is advantageous to compare the systems according to the number of H atoms bound to the Ti atoms because of obvious similarities in metal-C bonding. Therefore, the next system of discussion is $\mathrm{H}_{2} \mathrm{TiC}_{4} \mathrm{H}_{4}$. Geometry optimization at all levels of theory lead to a molecule of $C_{2 v}$ symmetry with all Ti and C atoms in a plane along with the $\mathrm{C}-\mathrm{H}$ bonds. B3LYP/TZV bond lengths and angles can be found in Table 4 and Figure 1C. Results for the other methods and basis are given in Table SI in Supporting Information. The B3LYP/TZV Ti-C bond length of $2.03 \AA$ is

TABLE 4: B3LYP/TZV Bond Lengths and Angles for $\mathbf{H}_{n} \mathbf{T i C}_{m} \mathbf{H}_{m}$

|  | $\mathrm{H}_{2} \mathrm{TiC}_{2} \mathrm{H}_{2}$ | $\mathrm{H}_{2} \mathrm{TiC}_{4} \mathrm{H}_{4}$ | $\mathrm{HTiC}_{3} \mathrm{H}_{3}$ | $\mathrm{HTiC}_{5} \mathrm{H}_{5}$ |
| :--- | :---: | :---: | :---: | :---: |
| $r_{\mathrm{Ti}-\mathrm{C}}(\AA \AA)$ | 1.99 | 2.03 | 1.89 | 1.93 |
| $r_{\mathrm{Ti}-\mathrm{H}}(\AA)$ | 1.74 | 1.71 | 1.77 | 1.76 |
| $r_{\mathrm{C}-\mathrm{C}}(\AA)$ | 1.32 | 1.36 | 1.44 | 1.39 |
| $r_{\mathrm{H}-\mathrm{C}}(\AA)$ |  | 1.49 |  | 1.44 |
|  | 1.08 | 1.08 | 1.08 | 1.08 |
|  |  | 1.09 | 1.09 | 1.09 |
| $\alpha(\mathrm{CTiC})$ | 39.35 | 94.94 | 83.10 | 99.40 |
| $\alpha(\mathrm{TiCC})$ | 70.33 | 98.77 | 77.57 | 86.06 |
| $\alpha(\mathrm{CCC})$ |  | 123.76 | 121.78 | 123.36 |
|  |  |  |  | 125.98 |

$0.04 \AA$ i longer than the corresponding bond in $\mathrm{H}_{2} \mathrm{TiC}_{2} \mathrm{H}_{2}$. The $\mathrm{C}-\mathrm{C}$ bonds adjacent to the $\mathrm{Ti}-\mathrm{C}$ bonds are $1.36 \AA$, and the single $\mathrm{C}-\mathrm{C}$ bond opposite the Ti atom is $1.49 \AA$. The bond lengths indicate that there is double bond character in the $\mathrm{C}-\mathrm{C}$ bonds adjacent to the $\mathrm{Ti}-\mathrm{C}$ bonds, and this is confirmed by NRT results. This $\mathrm{C}-\mathrm{C}$ double bond is $0.04 \AA$ longer than the $\mathrm{C}-\mathrm{C}$ bond of $\mathrm{H}_{2} \mathrm{TiC}_{2} \mathrm{H}_{2}$ corresponding to a slightly more delocalized double bond. The $\mathrm{H}-\mathrm{Ti}$ bonds are $1.71 \AA$, or 0.03 $\AA$ shorter than in $\mathrm{H}_{2} \mathrm{TiC}_{2} \mathrm{H}_{2}$. Mulliken population charges indicate the Ti charge is $+0.75 e$ or $0.03 e$ more positive than the Mulliken charge on the Ti atom in $\mathrm{H}_{2} \mathrm{TiC}_{2} \mathrm{H}_{2}$ whereas the $(\mathrm{H}-\mathrm{Ti}) \mathrm{H}$ atom charge of $-0.16 e$ is less negative, $0.02 e$, than the corresponding H in $\mathrm{H}_{2} \mathrm{TiC}_{2} \mathrm{H}_{2}$. Mulliken charges on the C -ring atoms are $-0.43 e$ for the carbons adjacent to the metal center and $-0.14 e$ on the remaining $C$. The average charge on the carbon atoms is $-0.28 e$, which is $0.07 e$ less than the Mulliken charges on the C atoms in $\mathrm{H}_{2} \mathrm{TiC}_{2} \mathrm{H}_{2}$.

NRT bond orders and significant resonance structures are provided in Table 3 and Figure 2. The primary resonance structure shows a contribution of $69.7 \%$ and corresponds to single $\mathrm{Ti}-\mathrm{C}$ bonds, a single bond between the two carbons at the end opposite the Ti , and double bonds between the remaining C atoms. The remaining resonance structures each have a $6.3 \%$ contribution and correspond to interchanging double and single bonds between the Ti and C atoms. The B3LYP/TZV NRT gives a bond order near 1.0 for each $\mathrm{Ti}-\mathrm{C}$ bond and near 1.0 for each $\mathrm{Ti}-\mathrm{H}$ bond. As with $\mathrm{H}_{2} \mathrm{TiC}_{2} \mathrm{H}_{2}$, the $\mathrm{Ti}-\mathrm{C}$ bond has a large ionic character. The $\mathrm{Ti}-\mathrm{H}$ bond is, however, less ionic than the $\mathrm{Ti}-\mathrm{H}$ bond in $\mathrm{H}_{2} \mathrm{TiC}_{2} \mathrm{H}_{2}$. The $\mathrm{C}-\mathrm{C}$ bond adjacent to the $\mathrm{Ti}-\mathrm{C}$ bond has a bond order of 1.9 , which is only slightly less than the $\mathrm{C}-\mathrm{C}$ bond of $\mathrm{H}_{2} \mathrm{TiC}_{2} \mathrm{H}_{2}$. As with $\mathrm{H}_{2} \mathrm{TiC}_{2} \mathrm{H}_{2}$, bond strain occurs between the $\mathrm{Ti}-\mathrm{C}$ bonds; however, bond strain is less with the five-member ring.

The next system of interest is titanacyclobutadiene, $\mathrm{HTiC}_{3} \mathrm{H}_{3}$. Before discussion of the results of $\mathrm{HTiC}_{3} \mathrm{H}_{3}$, there are two isovalent molecules that require consideration: cyclobutadiene and silacyclobutadiene. At the moment, we will consider only the lowest-lying electronic state of these molecules, which in each case is a singlet. Theory predicts ${ }^{22}$ and experiment indicates ${ }^{23}$ that the ground-state structure of cyclobutadiene is rectangular with $D_{2 h}$ symmetry. The unequal bond lengths suggest two localized double bonds and are considered to be caused by the molecule's antiaromatic $\pi$ system. ${ }^{24}$ Experimental $^{25}$ and theoretical ${ }^{26}$ work on silacyclobutadiene show the molecule to be planar with $C_{s}$ symmetry, and all four ring bonds having different lengths. Both $\mathrm{Si}-\mathrm{C}$ bond lengths and $\mathrm{C}-\mathrm{C}$ bond lengths are different, indicating localized double bonds.

Unlike cyclobutadiene and silacyclobutadiene, the geometry of titanacyclobutadiene shows two equivalent $\mathrm{Ti}-\mathrm{C}$ bonds and two equivalent $\mathrm{C}-\mathrm{C}$ bonds; B3LYP/TZV bond lengths and angles can be found in Table 4. Results for the remaining
methods are in given in Table SII in Supporting Information. All methods optimize to $C_{2 v}$ symmetry with the given basis sets except for the BLYP. ${ }^{27}$ The RHF/TZV Ti-C bond lengths are $1.91 \AA$ and are 0.03 and $0.02 \AA$ long compared to MP2/TZV and B3LYP/TZV, respectively, whereas the RHF/TZV C-C bond lengths are $1.43 \AA$ and are $0.01 \AA$ short relative to both MP2/TZV and B3LYP/TZV. This is consistent with the previous titanacycloalkenes where the RHF metal-carbon bond lengths are longer than the "correlated" techniques and the $\mathrm{C}-\mathrm{C}$ bond lengths are shorter than the "correlated" methods. Vibrational frequencies and relative intensities for the B3LYP/TZV can be found in Table 5.

The RHF/TZV HOMO-LUMO gap is small and suggests the possibility of a low-lying triplet state. This is consistent with cyclobutadiene and silacyclobutadiene, which have singlettriplet splittings of $6{ }^{22}$ and $5 \mathrm{kcal} / \mathrm{mol},{ }^{26,28}$ respectively. At the ROHF level of theory, calculations on $\mathrm{HTiC}_{3} \mathrm{H}_{3}$ reveal the triplet state to be lower in energy by $24.5 \mathrm{kcal} / \mathrm{mol}$. Calculations with ROB3LYP/TZV, ROBLYP/TZV, and ROMP2/TZV, however, place the singlet state as the ground state by $14.4,22.0$, and $27.6 \mathrm{kcal} / \mathrm{mol}$, respectively. These methods yield a greater singlet-triplet splitting than found in silacyclobutadiene ${ }^{28}$ and correspondingly indicate greater aromatic character. We present an explanation for possible aromaticity within this $4 \pi$ electron ring in the section on bonding below. Geometries for the triplet state with the TZV basis and the various methods are provided in Table SIII in Supporting Information. For all of the theoretical methods except RHF, the triplet state exhibits only a slight asymmetry. For example, the $\mathrm{Ti}-\mathrm{C}$ bond lengths and the $\mathrm{C}-\mathrm{C}$ bond lengths differ by less than $0.001 \AA$. By contrast, the RHF/ TZV Ti-C bond lengths differ by $0.01 \AA$ and the $\mathrm{C}-\mathrm{C}$ by 0.09 A.

NRT bond orders and significant resonance structures for the singlet state are provided in Table 3 and Figure 2. The B3LYP/ TZV NRT gives a bond order of 1.40 for both of the $\mathrm{Ti}-\mathrm{C}$ bonds and 1.43 for both of the $\mathrm{C}-\mathrm{C}$ bonds. The nearequivalence in the pair of $\mathrm{Ti}-\mathrm{C}$ and the pair of $\mathrm{C}-\mathrm{C}$ bond orders is consistent with the equal bond lengths and suggests significant delocalization within the ring. Relative to the previous systems studied, the larger $\mathrm{Ti}-\mathrm{C}$ bond orders in $\mathrm{HTiC}_{3} \mathrm{H}_{3}$ compared to $\mathrm{H}_{2} \mathrm{TiC}_{2} \mathrm{H}_{2}$ and $\mathrm{H}_{2} \mathrm{TiC}_{4} \mathrm{H}_{4}$ are expected on the basis of simple valence electron count. That is, $\mathrm{H}-\mathrm{Ti}$ has three electrons to contribute in bonding to the carbon framework (two $\sigma$ and one $\pi$ bond), whereas $\mathrm{H}_{2} \mathrm{Ti}$ has only two electrons to contribute (two $\sigma$ bonds). The $\mathrm{Ti}-\mathrm{H}$ bond in $\mathrm{HTiC}_{3} \mathrm{H}_{3}$ is also more ionic than the previous systems. As expected, the $\mathrm{Ti}-\mathrm{H}$ bond order is near 1.0 and highly ionic, $48 \%$, whereas the corresponding $\mathrm{Ti}-\mathrm{H}$ bonds in $\mathrm{H}_{2} \mathrm{TiC}_{2} \mathrm{H}_{2}$ and $\mathrm{H}_{2} \mathrm{TiC}_{4} \mathrm{H}_{4}$ were $38 \%$ and $29 \%$ ionic, respectively. The other $\mathrm{C}-\mathrm{H}$ bond orders are also near 1.0 and are primarily covalent. NRT shows two primary structures of equal weights of $28.3 \%$ contribution and correspond to alternating double bonds. The third resonance structure contributes $5.9 \%$; it is a result of the d orbitals on Ti and would not likely be present in cyclobutadiene or silacyclobutadiene. As with $\mathrm{H}_{2} \mathrm{TiC}_{2} \mathrm{H}_{2}$ and $\mathrm{H}_{2} \mathrm{TiC}_{4} \mathrm{H}_{4}$, bond strain occurs between the $\mathrm{Ti}-\mathrm{C}$ bonds.

The final molecule studied is $\mathrm{HTiC}_{5} \mathrm{H}_{5}$ or titanabenzene. Geometry optimization of titanabenzene at all levels of method and basis indicates the structure to have a boat-shaped or Dewar geometry, with the Ti atom and the para-C atom sitting above a plane of four carbon atoms as shown in Figure 1D. The symmetry of the molecule is $C_{s}$, with a single plane of symmetry passing through the $\mathrm{Ti}-\mathrm{H}$ bond and the para- $\mathrm{C}-\mathrm{H}$ bond. The energy difference between the optimal planar conformation and

the boat-shaped molecule is $22.7 \mathrm{kcal} / \mathrm{mol}$ with B3LYP/TZV functional and basis. In summary of the B3LYP/TZV results of Table 4, the $\mathrm{Ti}-\mathrm{C}$ bond length of $1.93 \AA$ is $0.04 \AA$ longer than the corresponding bond in $\mathrm{HTiC}_{3} \mathrm{H}_{3}$. The CC bonds adjacent to the $\mathrm{Ti}-\mathrm{C}$ bonds are $1.39 \AA$, and the single $\mathrm{C}-\mathrm{C}$ bonds opposite the Ti atom are $1.44 \AA$. These bond lengths differ by less than $0.05 \AA$, indicating that there is some double bond character in both of the $\mathrm{C}-\mathrm{C}$ bonds, and this is confirmed by AIM and NRT results. The B3LYP/TZV C-C bond length in $\mathrm{HTiC}_{3} \mathrm{H}_{3}$ is the same length, $1.44 \AA$, as the para/meta $\mathrm{C}-\mathrm{C}$ bond, confirming the somewhat delocalized nature of the $\mathrm{C}-\mathrm{C}$ bonds in $\mathrm{HTiC}_{5} \mathrm{H}_{5}$. Mulliken charges indicate the Ti atom charge is $+0.75 e$, the ortho- C atom charge is $-0.38 e$, the meta- C atom charge is $-0.18 e$, and the para-C atom charge is $-0.27 e$. The distance from the Ti atom to para-C atom is $2.31 \AA$ and is 0.01 $\AA$ greater than the distance from the meta-C atom. Yet the larger charge on the para-C atom and the boat-shaped geometry of the molecule indicate charge transfer taking place between the para-C atom and the Ti atom. Structural data for all methods are given in Table SIV in Supporting Information. All methods compare well, with the greatest differences being between the MP2/ECP and the B3LYP/ECP. Here, the MP2/ECP method predicts longer bond lengths than any other method, whereas the B3LYP/ECP compares more favorably with the TZV results of the other methods. The MP2/TZV method was not done because of resource limitations; however, on the basis of results from previous systems, it should compare well with B3LYP.

NRT bond orders and significant resonance structures are provided in Table 3 and Figure 2. The B3LYP/TZV NRT gives a $\mathrm{Ti}-\mathrm{C}$ bond order of 1.27 and $\mathrm{C}-\mathrm{C}$ bond orders of 1.59 for the bonds adjacent to the $\mathrm{Ti}-\mathrm{C}$ bond and 1.23 for the $\mathrm{C}-\mathrm{C}$ bonds opposite the $\mathrm{Ti}-\mathrm{C}$ bond. There is a weak bond of order 0.26 between the Ti atom and the para- C atom in the boatshaped structure. The NRT results shown in Figure 2 make clear that the molecule exhibits a complex electronic structure. For
example, the highest weight resonance structure contributes only 13.2\%. The three other structures shown in Figure 2 average only $7 \%$ each. There are a large number of structures, not shown, that contribute less than $5 \%$ each. Two resonance structures with weight of $6.6 \%$ are benzene-like with alternating double bonds. The primary resonance structure, however, shows a contribution of $13.2 \%$ and corresponds to a lone pair on the para-C atom and double $\mathrm{C}-\mathrm{C}$ bonds adjacent to the $\mathrm{Ti}-\mathrm{C}$ bonds. The next most significant resonance structure, $7.8 \%$ contribution, replaces the lone pair of the first resonance structure with a bond between the Ti atom and the para- C atom. These resonance structures indicate an interaction that is both consistent with the Mulliken charges and the boat structure of the molecule. Though less than the smaller systems discussed in this work, AIM critical points show bond strain between the $\mathrm{Ti}-\mathrm{C}$ bonds. AIM also indicates the existence of a critical point midway between the Ti atom and the para-C atom, again supporting a weak "bonding" interaction between the Ti atom and the para-C atom. The interaction of the Ti atom with the para- C atom can be explained by considering an available d orbital on the Ti center. The mechanism for this long bond interaction can be explained in terms of orbital diagrams and is discussed below.

## Overall Bonding

The initial interaction between a bare transition metal and ethene is often described by ethene donation of $\pi$-electron density to an empty $\sigma$-orbital of the metal atom. This weakens the $\pi$-bond of ethene and lowers the $\pi^{*}$-orbital energy. Electrons are then accepted from a back-donating d-orbital of the metal atom. ${ }^{29}$ The above model is used when describing a bare transition metal approaching an unsaturated hydrocarbon. In the evaluation of the bonding in the systems of this study, however, we must consider the H atoms bound to the Ti metal center. It would be better to consider a $\mathrm{TiH}_{2}$ approaching ethyne, as in

Figure 4. Energy level diagram of $\mathrm{TiH}_{2}$ and $\mathrm{C}_{2} \mathrm{H}_{2}$ forming molecular $\mathrm{H}_{2} \mathrm{TiC}_{2} \mathrm{H}_{2}$.

Figure 5. Schematics of the bonding orbitals of $\mathrm{TiH}_{2}$ and $\mathrm{C}_{2} \mathrm{H}_{2}$.
the similar dihydride dihydrogen metal complexes. ${ }^{30} \mathrm{TiH}_{2}$ is a bent molecule ${ }^{31}$ with a ${ }^{3} \mathrm{~B}_{1}$ ground state. The dipole moment of the molecule indicates a positive charge on the Ti atom. Initially considering the Ti end of $\mathrm{H}_{2} \mathrm{Ti}$ as approaching a $\mathrm{C}_{2} \mathrm{H}_{2}$ triple bond, the diffuse $\pi$-electrons of $\mathrm{C}_{2} \mathrm{H}_{2}$ would be polarized toward the Ti metal center. A molecular orbital energy level diagram for this process is presented in Figure 4. This representation shows overlap between the $\mathrm{a}_{1}$ orbital of $\mathrm{TiH}_{2}$ and the $\pi$-bonding $\mathrm{a}_{1}$ orbital of $\mathrm{C}_{2} \mathrm{H}_{2}$ and overlap between the $\mathrm{b}_{1}$ orbital of $\mathrm{TiH}_{2}$ and the $\pi^{*}$-nonbonding $\mathrm{b}_{1}$ orbital of $\mathrm{C}_{2} \mathrm{H}_{2}$. A schematic representation of the orbital interactions is provided in Figure 5 where the $\mathrm{a}_{1}$ and $\mathrm{b}_{1}$ orbitals of Ti are $\mathrm{d}_{z^{2}}$ and $\mathrm{d}_{x z}$ atomic orbitals, respectively. The reaction energy for our model process $\left(\mathrm{TiH}_{2}+\mathrm{C}_{2} \mathrm{H}_{2}\right)$ with the B3LYP/TZV is $-48.4 \mathrm{kcal} / \mathrm{mol}$, whereas the reaction energy for the matrix isolation based process of a bare $\mathrm{Ti}\left({ }^{3} \mathrm{~F}\right)$ atom reacting with $\mathrm{C}_{2} \mathrm{H}_{4}$ with the same method and basis is $-10.7 \mathrm{kcal} / \mathrm{mol} .{ }^{32}$ A similar description can be made for the five-member ring $\mathrm{H}_{2} \mathrm{TiC}_{4} \mathrm{H}_{4}$ and will not be presented in this work. The energy of reaction, however, for butadiene with a bare $\mathrm{Ti}\left({ }^{3} \mathrm{~F}\right)$ atom to yield titanacyclopentadiene with the B3LYP/TZV is $-76.8 \mathrm{kcal} / \mathrm{mol}$. This value is based on the difference in the computed energy of the product and reactants and does not consider zero-point energy corrections.

Bonding in the four-membered ring, $\mathrm{HTiC}_{3} \mathrm{H}_{3}$, can be considered in many ways. Perhaps the simplest pathway is to consider a $\mathrm{HTi}\left({ }^{4} \mathrm{~B}_{1}\right)$ fragment inserting into a planar- $\mathrm{C}_{2 v} \mathrm{C}_{3} \mathrm{H}_{3}$ $\left({ }^{4} B_{1}\right)$. With this simple picture we can construct an energy level diagram where the singly occupied symmetry orbitals $b_{2}, a_{1}$, and $a_{2}$ from each fragment pair up. This idealized picture could also be applied to a CH fragment to yield cyclobutadiene and SiH fragment to yield silacyclobutadiene. The ground-state geometry of these latter two molecules is of $D_{2 h}$ and $C_{s}$ symmetry, respectively, and consists of localized double bonds. The delocalization in the Ti-bearing molecule is due to the availability of the $\mathrm{Ti}_{x y}$ atomic orbital to the $\mathrm{a}_{2}$ molecular orbital as shown in Figure 6. The overlap between the HTi d orbital and the $\mathrm{C}_{3} \mathrm{H}_{3} \pi$-system allows electron delocalization and constitutes a molecule with aromatic character. Though currently of interest, ${ }^{33}$ we do not wish to argue the nature of aromaticity

$\mathrm{a}_{2}$

Figure 6. Schematics of the $\mathrm{a}_{2}$ bonding orbitals of TiH and $\mathrm{C}_{3} \mathrm{H}_{3}$.

Figure 7. (a) Contour diagram of the HOMO orbital of the planar conformer of $\mathrm{HTiC}_{5} \mathrm{H}_{5}$. The chosen plane is perpendicular to the molecular plane and exhibits the Ti atom and the para-C atom. (b) Contour diagram of the same orbital in the boat-shaped conformation of $\mathrm{HTiC}_{5} \mathrm{H}_{5}$. The ""*" indicates a bond critical point between Ti and C .
here but present a system that is apparently aromatic. The energy of reaction of allene with a bare $\operatorname{Ti}\left({ }^{3} \mathrm{~F}\right)$ atom to yield titanacyclobutadiene with the B3LYP/TZV is $-32.7 \mathrm{kcal} / \mathrm{mol}$. As with titanacyclopentadiene, zero-point energy corrections are not included.

Titanabenzene is isovalent to benzene and silabenzene. A number of studies on silabenzene ${ }^{34}$ have been performed and indicate that the geometry of the molecule is planar. In our study the first three molecules are planar whereas the ground state of titanabenzene is calculated to have a boat-shaped or Dewar conformation. This is not consistent with benzene or silabenzene. So why is this six-member ring not planar? From Mulliken charges, the Ti atom is positive and is therefore polarizing electrons from the $\pi$-network of the ring, similar to placing a positive charge in the molecular plane of benzene. From the NRT results in Figure 2, the double bonds of both the five- and six-member rings are localized to the $\mathrm{C}-\mathrm{C}$ bonds adjacent to the $\mathrm{Ti}-\mathrm{C}$ bonds. In the case of the six-member ring, the first
resonance structure suggests a lone pair of electrons on the para-C atom and the second structure denotes a bond connecting the para- C atom with the Ti atom. Expecting less interaction between Ti and the para-C atom, NRT of the planar $\mathrm{HTiC}_{5} \mathrm{H}_{5}$ decreases the resonance contribution by $1.4 \%$ and gives a bond order of 0.13 . The para-C atom "out-of-plane" p orbital is thus liberated to interact with an available d orbital on Ti. The folding of the molecule from planar to boat form reduces the Mulliken charge on the Ti atom from $+0.90 e$ to $+0.75 e$ where the electrons are coming from the para-C atom. The bonding between the para-C atom and the Ti atom therefore consists of a bent $\sigma$-bond across the ring. A cross-sectional contour plot of the orbital of interest in the planar and Dewar structure is shown in parts a and b of Figure 7, respectively. Figure 7a is a contour diagram of the nonbonding valence molecular orbital on the Ti and the para-C atom in the planar conformation. Figure 7 b is a contour diagram of the same orbital in the Dewar conformation, revealing the overlap of orbitals to form the bent $\sigma$-bond.

## Conclusion

In summary of the present work, $\mathrm{H}_{2} \mathrm{TiC}_{2} \mathrm{H}_{2}, \mathrm{HTiC}_{3} \mathrm{H}_{3}$, and $\mathrm{H}_{2} \mathrm{TiC}_{4} \mathrm{H}_{4}$ are planar molecules of $C_{2 v}$ symmetry. The sixmember ring has a boat-shaped structure caused by $\sigma$-bonding between the para-C atom and a Ti d orbital. According to NRT results, double bonds are primarily localized away from the Ti center, with the exception of $\mathrm{HTiC}_{3} \mathrm{H}_{3}$. The ground singlet state of titanacyclobutadiene shows aromatic character, which is contradictory to cyclobutadiene and silacyclobutadiene. The triplet state of titancyclobutadiene is calculated to be $14.4 \mathrm{kcal} /$ mol above the singlet with the B3LYP functional. Bader analysis of critical points shows considerable bond strain in the $\mathrm{Ti}-\mathrm{C}$ bonds and very little bond strain in the $\mathrm{C}-\mathrm{C}$ bonds.

(27) In the BLYP density functional optimized geometry the $\mathrm{H}-\mathrm{Ti}$ bond makes an angle of about $40.5^{\circ}$ with the CTiC plane. And, as with the HTiH plane in $\mathrm{H}_{2} \mathrm{TiC}_{2} \mathrm{H}_{2}$, the addition of the two f basis functions to the TZV basis set optimizes the molecule to the planar $C_{2 v}$ geometry with the BLYP functional.
