#### Abstract

Atomization energies at 0 K and heats of formation at 0 and 298 K are predicted for the borane compounds $\mathrm{H}_{(3-n)} \mathrm{BX}$ n for $\left(\mathrm{X}=\mathrm{F}, \mathrm{Cl}, \mathrm{Br}, \mathrm{I}, \mathrm{NH}_{2}, \mathrm{OH}\right.$, and SH$)$ and various radicals from coupled cluster theory $(\mathrm{CCSD}(\mathrm{T}))$ calculations with an effective core potential correlation-consistent basis set for I. In order to achieve near chemical accuracy ( $\pm 1.5 \mathrm{kcal} / \mathrm{mol}$ ), three corrections were added to the complete basis set binding energies calculated from frozen core coupled cluster theory energies: a correction for core-valence effects, a correction for scalar relativistic effects, and a correction for first-order atomic spin-orbit effects. Vibrational zero point energies were computed at the MP2 level. The calculated heats of formation are in excellent agreement with the available experimental data for the closed shell molecules, but show larger differences with the reported "experimental" values for the $\mathrm{BX}_{2}$ radicals. The heats of formation of the $\mathrm{BX}_{2}$ radicals were also calculated at the G3(MP2) level of theory, and the values were in excellent agreement with the more accurate CCSD(T) values. On the basis of extensive comparisons with experiment for a wide range of compounds, our calculated values for these radicals should be good to $\pm 1.5 \mathrm{kcal} / \mathrm{mol}$ and thus are to be preferred over the experimental values. The accurately calculated heats of formation allow us to predict the $\mathrm{B}-\mathrm{X}$ and $\mathrm{B}-\mathrm{H}$ adiabatic bond dissociation energies (BDEs) to within $\pm 1.5 \mathrm{kcal} / \mathrm{mol}$. The $\mathrm{B}-\mathrm{F}$ BDEs in the $\mathrm{H}_{(3-n)} \mathrm{BF}_{n}$ compounds and in $\mathrm{BF}\left({ }^{1} \Sigma^{+}\right)$are the largest BDEs in comparison to the other substituents that were investigated. The second and third largest $\mathrm{B}-\mathrm{X}$ BDEs in the $\mathrm{H}_{(3-n)} \mathrm{BX}$ and BX compounds are predicted for $\mathrm{X}=\mathrm{OH}$ and $\mathrm{NH}_{2}$, respectively. The substituents have a minimal effect on the $B-H$ BDEs in $\mathrm{HBX}_{2}$ and $\mathrm{H}_{2} \mathrm{BX}$ compared to the first $\mathrm{B}-\mathrm{H}$ BDE of borane. The differences in adiabatic and diabatic BDEs, which are related to the reorganization energy in the product, can be estimated from singlet-triplet splittings in these molecules, and can account for the large fluctuations in adiabatic BDEs observed, specifically for the $\mathrm{BX}_{2}$ and HBX radicals, during the stepwise loss of the respective substituents.

## Introduction

There is substantial interest in the energetics of borane compounds as intermediates in regeneration cycles for chemical hydrogen storage systems. We are especially interested in the $B-X$ and $B-H$ bond dissociation energies (BDEs) in the $B X_{3}$, $\mathrm{HBX}_{2}$, and $\mathrm{H}_{2} \mathrm{BX}$ compounds, as well as the radicals $\mathrm{BX}_{2}$ and HBX, which are products of varying bond breaking processes, where $\mathrm{X}=\mathrm{F}, \mathrm{Cl}, \mathrm{Br}, \mathrm{I}, \mathrm{NH}_{2}, \mathrm{OH}$, and SH , for use in the investigation of the thermodynamics of regeneration schemes for spent fuel derived from ammonia borane. These compounds have other applications and are of substantial interest as model systems. ${ }^{1}$ Following our recent work ${ }^{2}$ on the BDEs in the $\mathrm{PF}_{x} \mathrm{O}_{y}$ and $\mathrm{SF}_{x} \mathrm{O}_{y}$ compounds, we define the diabatic BDE as dissociation to the configurations most closely representing the bonding configuration in the reactant and the adiabatic BDE as dissociation to the ground-state of the separated species. The adiabatic BDE will always be equal to or less than the diabatic BDE. Because it can be difficult to measure BDEs, high-level theoretical calculations of these quantities offer a unique opportunity to obtain accurate self-consistent values for these processes.

There have been a number of measurements of BDEs for these borane compounds, but many of them have not been as accurate as one would hope for. ${ }^{3}$ The experimental dissociation energies for the diatomic haloboranes have been summarized

[^0]by Huber and Herzberg. ${ }^{4}$ The experimental heats of formation for the hydrogen halides, ${ }^{5}$ the haloboranes, ${ }^{6}$ the dihaloboranes (with the exception of diiodoborane), ${ }^{6}$ the dihaloboryl radicals, ${ }^{6}$ the trihaloboranes, ${ }^{5,6}$ trihydroxyborane, ${ }^{6}$ and the dihydroxyboryl radical ${ }^{6}$ have been reported. The BDEs of the borane compounds $\mathrm{B}(\mathrm{H})_{x}-\mathrm{H}$ for $x=0,1$, and 2 have been reported. ${ }^{7-9}$

Modern computational chemistry methods implemented on high-performance computer architectures can now provide reliable predictions of chemical bond energies to within about $1 \mathrm{kcal} / \mathrm{mol}$ for most compounds that are not dominated by multireference character. ${ }^{10} \mathrm{We}$ can use the approach that we have been developing with collaborators at Pacific Northwest Laboratory and Washington State University for the prediction of accurate molecular thermochemistry ${ }^{11}$ to predict BDEs in these boron compounds. Our approach is based on calculating the total atomization energy of a molecule and using this value with known heats of formation of the atoms to calculate the heat of formation at 0 K . The approach starts with coupled cluster theory with single and double excitations and includes a perturbative triples correction $(\operatorname{CCSD}(\mathrm{T})),{ }^{12-14}$ combined with the correlation-consistent basis sets ${ }^{15,16}$ extrapolated to the complete basis set limit to treat the correlation energy of the valence electrons. This is followed by a number of smaller additive corrections including core-valence interactions and relativistic effects, both scalar and spin-orbit. The zero point energy can be obtained from experiment, theory, or a combination of the two. Corrections to 298 K can then be calculated by
using standard thermodynamic and statistical mechanics expressions in the rigid rotor-harmonic oscillator approximation ${ }^{17}$ and appropriate corrections for the heat of formation of the atoms. ${ }^{18}$

There have been several theoretical investigations into a couple of the molecules under study. The heats of formation of some small halogenated compounds, including the hydrogen halides, have been previously calculated using a similar approach at the $\operatorname{CCSD}(\mathrm{T}) / \mathrm{CBS}$ level plus additional corrections. ${ }^{19}$ The authors noted that the largest errors in the calculated heats of formation were found for the molecules containing the I atom. In our recent study of the iodofluorides, ${ }^{20}$ we found that it was necessary to correlate the core electrons with the aug-cc$\mathrm{pwCV} n \mathrm{Z}$ basis sets for $n=\mathrm{D}$, T, or Q in order to extrapolate these quantities to the CBS limit to predict accurate heats of formation. The molecular atomization energies of $\mathrm{BF}_{3}$ and $\mathrm{BCl}_{3}$ have previously been reported at a comparable composite $\operatorname{CCSD}(\mathrm{T}) / \mathrm{CBS}$ level. ${ }^{11 \mathrm{i}}$ Martin and Taylor have reported on the atomization energies of BF and $\mathrm{BF}_{3}$ using the $\operatorname{CCSD}(\mathrm{T})$ method and used these results in an analysis of the heat of formation of the boron atom. ${ }^{21}$ Bauschlicher and Ricca have reported $\operatorname{CCSD}(\mathrm{T}) / \mathrm{CBS}$ heats of formation on the basis of the atomization energies obtained with the cc-pVnZ basis sets up through $n=$ 5 for $\mathrm{BF}_{n}, \mathrm{BF}_{n}{ }^{+}, \mathrm{BCl}$, and $\mathrm{BCl}_{n}{ }^{+}$for $n=1-3 .{ }^{22}$ Schlegel and Harris have reported the heats of formation of the $\mathrm{BH}_{m} \mathrm{Cl}_{n}$ species at the G-2 level of theory. ${ }^{23}$ Rablen and Hartwig have reported on the sequential BDEs of borane compounds at the G-2 and CBS-4 levels of theory. ${ }^{24}$ Baeck and Bartlett have studied $\mathrm{BCl}_{3}, \mathrm{BCl}_{2} \mathrm{BCl}$, and their anions and cations using the coupled-cluster and MBPT levels of theory and looked at their structure, spectra, and decomposition paths. ${ }^{25}$

Computational Approach. For the current study, we used the augmented correlation consistent basis sets aug-cc-pVnZ ( $n=\mathrm{D}, \mathrm{T}, \mathrm{Q}$ ) for $\mathrm{H}, \mathrm{B}, \mathrm{N}, \mathrm{O}, \mathrm{F}$, and $\mathrm{Br} .^{15,16}$ It has recently been found that tight $d$ functions are necessary for calculating accurate atomization energies for second row elements, ${ }^{26}$ so we also included additional tight $d$ functions in our calculations, giving the aug-cc-pV $(n+d) \mathrm{Z}$ basis set on the second row atoms S and Cl . The $\operatorname{CCSD}(\mathrm{T})$ total energies were extrapolated in the normal way to the CBS limit by using a mixed exponential/ Gaussian function of the form:

$$
\begin{equation*}
E(n)=E_{\mathrm{CBS}}+A \exp [-(n-1)]+B \exp \left[-(n-1)^{2}\right] \tag{1}
\end{equation*}
$$

with $n=2$ (aVDZ), 3 (aVTZ), and 4 (aVQZ), as first proposed by Peterson et al. ${ }^{27}$

In order to achieve thermochemical properties within $\pm 1$ $\mathrm{kcal} / \mathrm{mol}$ of experiment, it is necessary to account for core-valence correlation energy effects. Core-valence (CV) calculations were carried out with the weighted core-valence basis set cc-pwCVTZ. ${ }^{28}$ The core-valence correction is then taken as the difference in energy between the valence electron correlation calculation and that with the appropriate core electrons included using basis sets with additional functions.

For molecules containing I as a substituent, we used a different approach due to issues described elsewhere. ${ }^{20}$ For I, we used the new effective core potential/correlation consistent basis sets developed by Peterson and co-workers. ${ }^{29}$ These basis sets were developed in combination with the small core relativistic effective core potentials (RECPs) from the Stuttgart/ Köln group. The RECP for I subsumes the $\left(1 \mathrm{~s}^{2}, 2 \mathrm{~s}^{2}, 2 \mathrm{p}^{6}, 3 \mathrm{~s}^{2}\right.$, $3 \mathrm{p}^{6}, 3 \mathrm{~d}^{10}$ ) orbital space into the 28 -electron core set, leaving the $\left(4 s^{2}, 4 p^{6}, 5 s^{2}, 4 d^{10}\right.$ and $\left.5 p^{5}\right)$ space with 25 electrons to be handled explicitly. We performed our complete basis set extrapolation with the aug-cc-pwCVnZ basis sets for $n=\mathrm{D}$, $\mathrm{T}, \mathrm{Q}$ with 25 active electrons on each I atom so the core-valence
correction is automatically included in the CBS extrapolation. We use $\mathrm{aV} n \mathrm{Z}$ to represent the combination of aug-cc-pVnZ on $\mathrm{H}, \mathrm{B}, \mathrm{N}, \mathrm{O}, \mathrm{F}$, and Br and aug-cc-pV(n+d)Z on the second row atoms S and Cl . For the molecules containing I as a substituent, we also use $\mathrm{aV} n \mathrm{Z}$ to represent the combination of aug-cc-pwCVnZ on the other atoms and aug-cc-pwCVnZ-PP on I.

We also performed additional calculations for molecules containing Br using the new effective core potential/correlation consistent basis sets developed by Peterson and co-workers. ${ }^{29}$ The RECP subsumes the $\left(1 s^{2}, 2 s^{2}, 2 p^{6}\right)$ orbital space into the 10 -electron core set, leaving the ( $3 \mathrm{~s}^{2}, 3 \mathrm{p}^{6}, 4 \mathrm{~s}^{2}, 3 \mathrm{~d}^{10}$ and $4 \mathrm{p}^{5}$ ) space with 25 electrons to be handled explicitly, and only the $\left(n s^{2}, n^{5}\right.$ ) electrons are active in our valence correlation treatment. In these calculations, we will use aVnZ-PP to represent the combination of the aug-cc-pVnZ basis set on H and B and the aug-cc-pVnZ-PP basis set on Br . Core-valence calculations were also carried out with the weighted core-valence basis set cc-pwCVTZ for H and $\mathrm{B},{ }^{28}$ and the cc-pwCVTZ-PP basis set for Br , which is based on the cc-pVTZ-PP basis set and accompanying small core RECP. For Br, the cc-pwCVTZPP basis set includes up through g-functions in order to provide a consistent degree of angular correlation for the active 4 d electrons. The core-valence calculations for Br involve all 25 electrons outside the RECP core.

All of the current work was performed with the MOLPRO suite of programs. ${ }^{30}$ The open-shell $\operatorname{CCSD}(\mathrm{T})$ calculations for the atoms were carried out at the R/UCCSD(T) level. In this approach, a restricted open-shell Hartree-Fock (ROHF) calculation was initially performed, and the spin constraint was relaxed in the coupled cluster calculation. ${ }^{31-33}$ All of the calculations were done on the 144 processor Cray XD-1 computer system at the Alabama Supercomputer Center or a Dell cluster at the University of Alabama.

The geometries were optimized numerically for most of the molecules at the frozen core $\operatorname{CCSD}(\mathrm{T})$ level with the aVDZ and aVTZ correlation-consistent basis sets. The $\operatorname{CCSD}(\mathrm{T}) / \mathrm{aVTZ}$ geometries were then used in single-point $\operatorname{CCSD}(\mathrm{T}) / \mathrm{aVQZ}$ calculations. Diatomics were further optimized at the $\operatorname{CCSD}(\mathrm{T})$ / aVQZ level, and bond distances, harmonic frequencies, and anharmonic corrections were obtained from a fifth-order fit of the potential energy surface (PES) at this level. For the molecules containing I as a substituent, geometry optimizations were performed at the $\operatorname{CCSD}(\mathrm{T})$ level with the aVDZ-PP and aVTZ-PP basis sets and additionally with the aVQZ-PP basis set for the diatomic with a fit of the PES performed at this level. The $\operatorname{CCSD}(\mathrm{T}) / \mathrm{aVTZ}-\mathrm{PP}$ geometery was then used in singlepoint $\operatorname{CCSD}(\mathrm{T}) / \mathrm{aV} n \mathrm{Z}(n=\mathrm{D}, \mathrm{T}, \mathrm{Q})$ calculations. For $\mathrm{H}_{(3-n)} \mathrm{BX}_{n}$ ( $\mathrm{X}=\mathrm{OH}, \mathrm{NH}_{2}$ ), geometry optimizations were performed at the MP2/aVTZ level, ${ }^{34}$ and the MP2/aVTZ geometry was consequently used in single-point $\operatorname{CCSD}(\mathrm{T}) / \mathrm{aV} n \mathrm{Z}(n=\mathrm{D}, \mathrm{T}, \mathrm{Q})$ calculations.

The vibrational frequencies of the polyatomic molecules were calculated at the MP2/aVTZ level ${ }^{34}$ using the Gaussian program system ${ }^{35}$ in order to obtain the zero point energies and the thermal corrections at 298 K .

Two adjustments to the total atomization energy (TAE $=$ $\Sigma D_{0}$ ) are necessary in order to account for relativistic effects in atoms and molecules. The first correction lowers the sum of the atomic energies (decreasing TAE) by replacing energies that correspond to an average over the available spin multiplets with energies for the lowest multiplets, as most electronic structure codes produce only spin multiplet averaged wave functions. The atomic spin-orbit corrections are $\Delta E_{\mathrm{SO}}(\mathrm{B})=0.03 \mathrm{kcal} / \mathrm{mol}$,
$\Delta E_{\mathrm{SO}}(\mathrm{O})=0.22 \mathrm{kcal} / \mathrm{mol}, \Delta E_{\mathrm{SO}}(\mathrm{F})=0.39 \mathrm{kcal} / \mathrm{mol}, \Delta E_{\mathrm{SO}}(\mathrm{S})$ $=0.56 \mathrm{kcal} / \mathrm{mol}, \Delta E_{\mathrm{SO}}(\mathrm{Cl})=0.84 \mathrm{kcal} / \mathrm{mol}, \Delta E_{\mathrm{SO}}(\mathrm{Br})=3.50$ $\mathrm{kcal} / \mathrm{mol}$, and $\Delta E_{\mathrm{SO}}(\mathrm{I})=7.24 \mathrm{kcal} / \mathrm{mol}$ from the tables of Moore. ${ }^{36}$ A second relativistic correction to the atomization energy accounts for molecular scalar relativistic effects, $\Delta E_{\text {SR }}$. $\Delta E_{\mathrm{SR}}$ is taken as the sum of the mass-velocity and one-electron Darwin (MVD) terms in the Breit-Pauli Hamiltonian. ${ }^{37}$ We evaluated $\Delta E_{\mathrm{SR}}$ by using expectation values for the two dominant terms in the Breit-Pauli Hamiltonian, the so-called MVD corrections from configuration interaction singles and doubles (CISD) calculations. The quantity $\Delta E_{\text {SR }}$ was obtained from CISD wave function with a VTZ basis set at the $\operatorname{CCSD}(\mathrm{T})$ / aVTZ, $\operatorname{CCSD}(\mathrm{T}) / \mathrm{aVTZ}-\mathrm{PP}$, or MP2/aVTZ geometry. The CISD (MVD) approach generally yields $\Delta E_{\mathrm{SR}}$ values in good agreement ( $\pm 0.3 \mathrm{kcal} / \mathrm{mol}$ ) with more accurate values from, for example, Douglass-Kroll-Hess (DKH) calculations, for most molecules. A potential problem arises in computing the scalar relativistic corrections for the molecules in this study, as there is the possibility of "double counting" the relativistic effect on I when applying an MVD correction to an energy that already includes most of the relativistic effects via the RECP. Because the MVD operators mainly sample the core region where the pseudo-orbitals are small, we assume any double counting to be small. For the molecules containing Br , the molecular scalar relativistic correction $\Delta E_{\mathrm{SR}}$ was calculated using the spin-free, one-electron DKH Hamiltonian. ${ }^{38-40} \Delta E_{\mathrm{SR}}$ was defined as the difference in the atomization energy between the results obtained from basis sets recontracted for DKH calculations ${ }^{39}$ and the atomization energy obtained with the normal valence basis set of the same quality. DKH calculations were carried out at the $\operatorname{CCSD}(\mathrm{T}) / \mathrm{cc}-\mathrm{pVTZ}$ and $\operatorname{CCSD}(\mathrm{T}) / \mathrm{cc}-\mathrm{pVTZ}-\mathrm{DK}$ levels of theory.

By combining our computed $\Sigma D_{0}$ values with the known heats of formation at 0 K for the elements ${ }^{6} \Delta H_{\mathrm{f}}^{0}(\mathrm{H})=51.63 \mathrm{kcal}$ $\mathrm{mol}^{-1}, \Delta H_{\mathrm{f}}^{0}(\mathrm{~B})=135.1 \pm 0.2 \mathrm{kcal} \mathrm{mol}^{-1},{ }^{41} \Delta H_{\mathrm{f}}^{0}(\mathrm{~N})=112.53$ $\mathrm{kcal} \mathrm{mol}{ }^{-1}, \Delta H_{\mathrm{f}}^{0}(\mathrm{O})=58.99 \mathrm{kcal} \mathrm{mol}^{-1}, \Delta H_{\mathrm{f}}^{0}(\mathrm{~F})=18.47 \mathrm{kcal}$ $\mathrm{mol}^{-1}, \Delta H_{\mathrm{f}}^{0}(\mathrm{~S})=65.66 \mathrm{kcal} \mathrm{mol}^{-1}, \Delta H_{\mathrm{f}}^{0}(\mathrm{Cl})=28.59 \mathrm{kcal} \mathrm{mol}^{-1}$, $\Delta H_{\mathrm{f}}^{0}(\mathrm{Br})=28.19 \mathrm{kcal} \mathrm{mol}^{-1}$, and $\Delta H_{\mathrm{f}}^{0}(\mathrm{I})=25.61 \mathrm{kcal} \mathrm{mol}^{-1}$, we can derive $\Delta H_{\mathrm{f}}^{0}$ values for the molecules under study in the gas phase. The heat of formation of the boron atom has changed over time. The original JANF value ${ }^{6}$ was $\Delta H_{\mathrm{f}}^{0}(0 \mathrm{~K}, \mathrm{~B})=132.7$ $\pm 2.9 \mathrm{kcal} / \mathrm{mol}$. Storms and Mueller ${ }^{42}$ recommended a much larger value of $136.2 \pm 0.2 \mathrm{kcal} / \mathrm{mol}$, which, on the basis of the analysis of Ruscic and co-workers, ${ }^{43}$ we have used in our previous work. ${ }^{44-46}$ Martin and Taylor ${ }^{47}$ calculated the atomization energies of BF and $\mathrm{BF}_{3}$ using a composite approach based on $\operatorname{CCSD}(\mathrm{T})$, used these results to analyze of the heat of formation of the boron atom, and came to a similar conclusion as that of Ruscic. ${ }^{43}$ More recently, Karton and Martin ${ }^{41}$ revised their heat of formation of the B atom to $135.1 \pm 0.2 \mathrm{kcal} / \mathrm{mol}$ on the basis of the experimental heats of formation of $\mathrm{BF}_{3}{ }^{5}$ and $\mathrm{B}_{2} \mathrm{H}_{6}{ }^{48}$ coupled with W4 calculations of their total atomization energies, and this is the value we have used. We obtain heats of formation at 298 K by following the procedures outlined by Curtiss et al. ${ }^{18}$

## Results and Discussion

Geometries. The calculated geometry parameters with the aVTZ basis set are given in Table 1 and are in excellent agreement with the available structural data. ${ }^{49}$ The electronic states and symmetry of the molecules are also given in Table 1 and consequently have been excluded from the other tables. The bond distance for the halide acids calculated with the aVDZ and aVTZ basis sets are given as Supporting Information (Table SM-1), and those for the remaining molecules calculated with
the aVDZ basis set are also given in the Supporting Information (Table SM-2). The total $\operatorname{CCSD}(\mathrm{T})$ energies as a function of the $\mathrm{aV} n \mathrm{Z}$ and aVnZ-PP ( $n=\mathrm{D}, \mathrm{T}, \mathrm{Q}$ ) basis sets are given in the Supporting Information in Tables SM-3 and SM-4, respectively. The calculated harmonic vibrational frequencies are also given as Supporting Information (Table SM-5). Finally, the components for the calculated atomization energies for the halide acids are given as Supporting Information (Table SM-6).

Heats of Formation. The energetic components for predicting the total molecular dissociation energies are given in Table 2, and we first describe some trends in the different components. The core-valence corrections for the molecules are all positive and range from $0.42(\mathrm{BCl})$ to $3.44 \mathrm{kcal} / \mathrm{mol}\left(\mathrm{B}\left(\mathrm{NH}_{2}\right)_{3}\right)$. The scalar relativistic corrections are all small and negative, and range in values from $-0.01(\mathrm{BI})$ to $-1.18\left(\mathrm{~B}(\mathrm{OH})_{3}\right) \mathrm{kcal} / \mathrm{mol}$, except for BBr with a $0.01 \mathrm{kcal} / \mathrm{mol}$ correction. We estimate that the error bars for the calculated heats of formation are $\pm$ $1.5 \mathrm{kcal} / \mathrm{mol}$ considering errors in the energy extrapolation, frequencies, and other electronic energy components. An estimate of the potential for significant multireference character in the wave function can be obtained from the $T_{1}$ diagnostic ${ }^{50}$ for the CCSD calculation. The value for the $T_{1}$ diagnostics are small ( $<0.03$ ) showing that the wave function is dominated by a single configuration. The $T_{1}$ diagnostics for the molecules are given as Supporting Information (Table SM-9).

The calculated heats of formation ${ }^{51}$ at 0 and 298 K are given in Table 3, where they are compared with available experimental data. We use the calculated values at 298 K in our discussions below unless specified otherwise. Our calculated heats of formation for the hydrogen halides $\mathrm{HX}(X=\mathrm{F}, \mathrm{Cl}, \mathrm{Br}, \mathrm{I})$ are in excellent agreement with the previously calculated ${ }^{19}$ and experimental values. ${ }^{5}$ Including the core electrons in the correlation and employing the weighted core basis sets for the CBS extrapolation, our calculated $\Delta \mathrm{H}_{\mathrm{f}}(\mathrm{HI})$ overestimates the experimental value by $0.5 \mathrm{kcal} / \mathrm{mol} .{ }^{5}$ Using the new heat of formation of the boron atom, we recalculated the values of $\Delta H_{\mathrm{f}}(\mathrm{BH}),{ }^{45} \Delta H_{\mathrm{f}}\left(\mathrm{BH}_{2}\right),{ }^{45} \Delta H_{\mathrm{f}}\left(\mathrm{BH}_{3}\right),{ }^{44}$ and $\Delta H_{\mathrm{f}}\left(\mathrm{BH}_{2} \mathrm{NH}_{2}\right),{ }^{44}$ as given in Table 3.

Our calculated value for the $\Delta H_{\mathrm{f}}(\mathrm{BF})$ is in excellent agreement with the value from a spectroscopic measurement, ${ }^{4}$ the experimental value derived from a mass spectrometry study of the $\mathrm{BF}_{2}$ radical, ${ }^{52}$ and the $\mathrm{JANAF}^{6}$ value (within the $\pm 3.3 \mathrm{kcal} /$ mol error bars of the latter). Our calculated value is in excellent agreement with the high-level theoretical values ${ }^{21,22}$ at the $\operatorname{CCSD}(\mathrm{T}) / \mathrm{CBS}$ level using basis sets up through aug-cc-pV6Z. The $\Delta H_{\mathrm{f}}(\mathrm{BF})$ at the lower G-2 and CBS-4 levels ${ }^{24}$ are in good agreement with our $\operatorname{CCSD}(\mathrm{T}) / \mathrm{CBS}$ value. Our calculated value for the $\Delta H_{\mathrm{f}}(\mathrm{BCl})$ is in excellent agreement with the experimental value derived from a thermochemical analysis of the dissociation energy of $\mathrm{BCl},{ }^{53}$ but differs from the JANAF value ${ }^{6}$ by $9.6 \mathrm{kcal} /$ mol and from the spectroscopically derived value ${ }^{4}$ by $5.8 \mathrm{kcal} /$ mol. The JANAF value was derived from the $\mathrm{Cl}_{2} \mathrm{~B}-\mathrm{Cl} \mathrm{BDE}$ and employing a ratio of the $D_{0}{ }^{\circ}(\mathrm{B}-\mathrm{F})$ /average bond energy of $\mathrm{BF}_{3}$. Our value should be accurate to $\pm 1.0 \mathrm{kcal} / \mathrm{mol}$ and supports the thermochemical value ${ }^{53}$ as the preferred experimental one. Our calculated value is also in excellent agreement with the $\operatorname{CCSD}(\mathrm{T}) / \mathrm{CBS}(\mathrm{V} n \mathrm{Z})$ theoretical value, ${ }^{22}$ and the G-2 value is in agreement with our more accurately calculated value. ${ }^{23}$ Our calculated values for the $\Delta H_{\mathrm{f}}(\mathrm{BBr})$ and $\Delta H_{\mathrm{f}}(\mathrm{BI})$ are in excellent agreement with the JANAF values ${ }^{6}$ within the rather large error bar limits of $\pm 10.0 \mathrm{kcal} / \mathrm{mol}$, and we expect our values to be accurate to within $\pm 1.5 \mathrm{kcal} / \mathrm{mol}$. Our $\Delta H_{\mathrm{f}}(\mathrm{BBr})$ differs by 2.5 and $8.8 \mathrm{kcal} / \mathrm{mol}$, respectively, from the spectroscopically derived values from Huber and Herzberg ${ }^{4}$

${ }^{a}$ Reference 4. ${ }^{b}$ Reference 49. ${ }^{c}$ Geometry parameters were obtained at the MP2 level.
and an infrared diode laser spectroscopy study of the vibrational levels, which were used to construct a potential energy curve. ${ }^{54}$

Our calculated values for the $\Delta H_{\mathrm{f}}\left(\mathrm{BF}_{3}\right), \Delta H_{\mathrm{f}}\left(\mathrm{BCl}_{3}\right)$, and $\Delta H_{\mathrm{f}}\left(\mathrm{BBr}_{3}\right)$ are in excellent agreement with the reported experimental values, ${ }^{6}$ within $0.5 \mathrm{kcal} / \mathrm{mol}$. Two high level calculated values ${ }^{11 i, 21}$ from similar $\operatorname{CCSD}(\mathrm{T}) / \mathrm{CBS}$ approaches are in agreement with our $\Delta H_{\mathrm{f}}\left(\mathrm{BF}_{3}\right)$ value. Our $\Delta H_{\mathrm{f}}\left(\mathrm{BCl}_{3}\right)$ is within $0.5 \mathrm{kcal} / \mathrm{mol}$ of the previously reported value at the $\operatorname{RCCSD}(\mathrm{T}) /$ CBS level. ${ }^{11 i}$ The G 2 value ${ }^{23}$ for the $\Delta H_{\mathrm{f}}\left(\mathrm{BCl}_{3}\right)$ is in good agreement with our higher level $\operatorname{CCSD}(\mathrm{T}) / \mathrm{CBS}$ value. Our $\Delta H_{\mathrm{f}}\left(\mathrm{BI}_{3}\right)$ is in agreement with the experimental value, ${ }^{6}$ determined from measuring the appearance potential of the $\mathrm{B}^{+}$ion from $\mathrm{BI}_{3}$, within the rather large error bar limits of $\pm 12.0 \mathrm{kcal} /$ mol. The $\Delta H_{\mathrm{f}}\left(\mathrm{B}(\mathrm{OH})_{3}\right)$ is calculated to be within $2.6 \mathrm{kcal} / \mathrm{mol}$
of the experimental value obtained from the heat of formation of the crystal and an average of the enthalpy of sublimation. ${ }^{6}$

Our calculated values for the $\Delta H_{\mathrm{f}}\left(\mathrm{HBF}_{2}\right)$ and $\Delta H_{\mathrm{f}}\left(\mathrm{HBCl}_{2}\right)$ are within $0.3 \mathrm{kcal} / \mathrm{mol}$ of the experimental values, ${ }^{6}{ }^{6}$ while the $\Delta H_{\mathrm{f}}\left(\mathrm{HBBr}_{2}\right)$ differs by $2.2 \mathrm{kcal} / \mathrm{mol}$. The G 2 values $^{23}$ for $\Delta H_{\mathrm{f}}\left(\mathrm{HBCl}_{2}\right)$ and $\Delta H_{\mathrm{f}}\left(\mathrm{H}_{2} \mathrm{BCl}\right)$ are in good agreement with our $\operatorname{CCSD}(\mathrm{T}) / \mathrm{CBS}$ values.

For our calculations on molecules containing Br , we note that there is a difference of $\sim 0.5 \mathrm{kcal} / \mathrm{mol}$ per Br atom in the valence electronic energy extrapolated to the CBS limit based on the $\mathrm{aV} n \mathrm{Z}$ and aVnZ-PP (Table SM-7) basis sets, respectively. However, much of the difference is recovered in the various components of the atomization energy, and the largest difference in the calculated heats of formation based on both approaches

${ }^{a}$ Extrapolated by using eq 1 with aVnZ, $n=\mathrm{D}, \mathrm{T}, \mathrm{Q} .{ }^{b}$ The zero point energies were obtained as described in the text. ${ }^{c}$ Core-valence corrections were obtained with the cc-pwCVTZ (B, $\mathrm{N}, \mathrm{O}, \mathrm{F}, \mathrm{S}, \mathrm{Cl}, \mathrm{Br}$ ) and cc-pwCVTZ basis sets at the optimized $\operatorname{CCSD}(\mathrm{T}) / \mathrm{aVTZ}$ or MP2/aVTZ geometries. For the compounds containing I, the CV correction is included in the CBS value, see text. ${ }^{d}$ The scalar relativistic correction is based on a CISD(FC)/ VTZ MVD calculation and is expressed relative to the CISD result without the MVD correction, i.e., including the existing relativistic effects resulting from the use of an RECP. ${ }^{e}$ Correction due to the incorrect treatment of the atomic asymptotes as an average of spin multiplets. Values are based on C. Moore's Tables, ref 36. ${ }^{f}$ The theoretical value of the dissociation energy to atoms $\Sigma D_{0}(0 \mathrm{~K})$.
was $0.7 \mathrm{kcal} / \mathrm{mol}$ for $\mathrm{BBr}_{3}$. The predicted heat of formation of $\mathrm{BBr}_{3}(\mathrm{aVnZ}-\mathrm{PP})$ of $-47.6 \mathrm{kcal} / \mathrm{mol}$ shows a larger difference of $1.2 \mathrm{kcal} / \mathrm{mol}$ from the experimental value. ${ }^{6}$ For the heats of formation for the I-containing molecules, the inclusion of the core electrons and the CBS extrapolation with the weighted core basis sets yields calculated values for the heats of formation that are on average within $0.3 \mathrm{kcal} / \mathrm{mol}$ of the heats of formation calculated using the aVnZ-PP basis sets and just correlating the valence electrons. The largest difference between the predicted heats of formation based on both approaches was $0.5 \mathrm{kcal} / \mathrm{mol}$ for $\mathrm{BI}_{3}$, where the heats of formation were predicted to be 8.6 (awCVnZ) and 9.1 (aVnZ-PP) $\mathrm{kcal} / \mathrm{mol}$, respectively, at 0 K .

Our calculated $\Delta H_{\mathrm{f}}\left(\mathrm{BF}_{2}\right)$ is in excellent agreement with the experimental value obtained from the thermochemical analysis of the $\mathrm{BF}_{2}$ radical by mass spectrometry differing by $1.3 \mathrm{kcal} / \mathrm{mol}$ and within the error bar limits. ${ }^{52}$ The JANAF value differs by 22 $\mathrm{kcal} / \mathrm{mol}$ and is clearly incorrect. ${ }^{6}$ The JANAF value ${ }^{6}$ was calculated based on combining the appearance potential of $\mathrm{BF}_{2}{ }^{+}$ from $\mathrm{BF}_{3}$ and the ionization potential for $\mathrm{BF}_{2}$. Using the same method, Margrave ${ }^{55}$ obtained a value of $\Delta_{\mathrm{f}} H^{\circ}\left(\mathrm{BF}_{2}, \mathrm{~g}\right) \leq-124 \pm$ $9 \mathrm{kcal} / \mathrm{mol}$, in better agreement with our reliably calculated value. Our $\Delta H_{\mathrm{f}}\left(\mathrm{BF}_{2}\right)$ is in excellent agreement with the $\operatorname{CCSD}(\mathrm{T}) / \mathrm{CBS}$ $(\mathrm{V} n \mathrm{Z})$ value. ${ }^{22}$ For the $\Delta H_{\mathrm{f}}\left(\mathrm{BCl}_{2}\right)$, there is a large difference of 12 $\mathrm{kcal} /$ mol between the $\mathrm{JANAF}^{6}$ and our calculated theoretical value. The JANAF value was determined based on an analysis of the equilibrium constants, which were obtained from ion intensity data, for the reaction $\mathrm{BCl}_{3}(\mathrm{~g})+\mathrm{BCl}(\mathrm{g})=2 \mathrm{BCl}_{2}(\mathrm{~g})$ in combination with the experimental enthalpies of formation for $\mathrm{BCl}_{3}(\mathrm{~g})$ and $\mathrm{BCl}(\mathrm{g}) .{ }^{6}$ Our calculated value for the $\Delta H_{\mathrm{f}}\left(\mathrm{BCl}_{2}\right)$ is in excellent agreement with the $\operatorname{CCSD}(\mathrm{T}) / \mathrm{CBS}(\mathrm{V} n \mathrm{Z})^{22}$ and G 2 values. ${ }^{23}$ Our $\Delta H_{\mathrm{f}}\left(\mathrm{BBr}_{2}\right)$ and $\Delta H_{\mathrm{f}}\left(\mathrm{BI}_{2}\right)$ differ by 9.2 and $1.8 \mathrm{kcal} / \mathrm{mol}$ from the estimated experimental values, which were based on an analogy with $\mathrm{BF}_{3}$, employing the ratio $\Delta_{\mathrm{r}} H^{\circ}\left(\mathrm{BX}_{3} \rightarrow \mathrm{BX}_{2}+\mathrm{X}\right) / \Delta_{\mathrm{r}} H^{\circ}\left(\mathrm{BX}_{3}\right.$ $\rightarrow \mathrm{B}+3 \mathrm{X}) .{ }^{6}$ Our $\Delta H_{\mathrm{f}}\left(\mathrm{B}(\mathrm{OH})_{2}\right)$ differs from the estimated experimental value by $15 \mathrm{kcal} / \mathrm{mol}$, which was calculated using the bond energy, $D_{0}{ }^{\circ}(\mathrm{B}-\mathrm{OH})$, of $132.7 \mathrm{kcal} / \mathrm{mol}$ and the enthalpies of formation of $\mathrm{B}(\mathrm{g})$ and $\mathrm{OH}(\mathrm{g})$ as 132.80 and $9.33 \mathrm{kcal} / \mathrm{mol}$, respectively. ${ }^{6}$ We recalculated the "experimental" $\Delta H_{\mathrm{f}}\left(\mathrm{B}(\mathrm{OH})_{2}\right)$ using the new value for $\Delta H_{\mathrm{f}}^{0}(\mathrm{~B})$ of $135.1 \pm 0.2 \mathrm{kcal} / \mathrm{mol}^{41}$ and $\Delta H_{\mathrm{f}}^{0}(\mathrm{OH})=8.85 \mathrm{kcal} / \mathrm{mol},{ }^{11 \mathrm{k}}$ and obtain a value of $-112.6 \mathrm{kcal} /$ mol, and still do not find agreement with our value. On the basis of extensive comparisons with experiment for a wide range of compounds, our calculated values for these radicals should be good to $\pm 1.5 \mathrm{kcal} / \mathrm{mol}$ and thus are to be preferred over the experimental values when there are large differences.

Bond Dissociation Energies. From the calculated heats of formation, we can predict the various $\mathrm{B}-\mathrm{X}$ and $\mathrm{B}-\mathrm{H}$ adiabatic BDEs at 0 K for $\mathrm{BX}_{3}, \mathrm{HBX}_{2}, \mathrm{H}_{2} \mathrm{BX}, \mathrm{BX}$, and HX as well as for the various radicals involved in the bond-breaking processes. The results are presented in Table 4 for comparison with the available experimental data, which is largely taken from the compilation of $L^{2}{ }^{3}$ and references therein. On the basis of the results for the heats of formation of the $\mathrm{BX}_{2}$ radicals, we expect that there are large errors in the experimental BDEs. We define the calculated BDE as the adiabatic value at 0 K . We first examine the BDEs in the diatomics $(\mathrm{B}-\mathrm{X})$, as they are representative of the strength of a single bond in these compounds. Our calculated value for the BDE of $\mathrm{BF}\left({ }^{1} \Sigma^{+}\right)$is in excellent agreement with the value from Huber and Herzberg, ${ }^{4}$ the reported experimental value of Hildebrand and Lau, ${ }^{52}$ and other calculations $(\operatorname{CCSD}(\mathrm{T}) / \mathrm{CBS}, \mathrm{G} 2$, and CBS-4) ${ }^{21,22,24}$ The $\mathrm{B}-\mathrm{F} \mathrm{BDE}$ is the largest $\mathrm{B}-\mathrm{X}$ bond energy. Our calculated $\mathrm{BCl}\left({ }^{1} \Sigma^{+}\right) \mathrm{BDE}$ differs by $1.2 \mathrm{kcal} / \mathrm{mol}$ from the thermochemical value, ${ }^{53} 5.8 \mathrm{kcal} / \mathrm{mol}$ from that of Huber and Herzber, ${ }^{4}$ and $8.0 \mathrm{kcal} / \mathrm{mol}$ from the JANAF value. ${ }^{6}$ Our calculated value is within $0.5 \mathrm{kcal} / \mathrm{mol}$ of another $\operatorname{CCSD}(\mathrm{T}) / \mathrm{CBS}$ value. ${ }^{22}$ The BDE of $\mathrm{BBr}\left({ }^{1} \Sigma^{+}\right)$falls within the range of the available experimental BDEs. ${ }^{6,54,56}$ The predicted $\mathrm{BI}\left({ }^{1} \Sigma^{+}\right) \mathrm{BDE}$ differs from the experimental value by $8 \mathrm{kcal} / \mathrm{mol} .^{3}$ Given the previously calculated $\Delta H_{\mathrm{f}}\left(\mathrm{NH}_{2}\right)^{11 \mathrm{~m}}$ and the experimental $\Delta H_{\mathrm{f}}(\mathrm{OH})^{11 \mathrm{k}}$ and $\Delta H_{\mathrm{f}}(\mathrm{SH}),{ }^{6}$ the $\mathrm{B}-\mathrm{X} \mathrm{BDE}$ in the pseudodiatomic molecules $\mathrm{B}\left(\mathrm{NH}_{2}\right), \mathrm{B}(\mathrm{OH})$, and $\mathrm{B}(\mathrm{SH})$ are calculated with the predicted $\mathrm{B}-\mathrm{OH}$ BDE lying just outside the error bar limits of the reported experimental value. ${ }^{48}$
$\mathrm{BF}_{3}$ is predicted to have the largest $\mathrm{X}_{2} \mathrm{~B}-\mathrm{X}$ BDE, and this $\mathrm{B}-\mathrm{F}$ BDE is slightly less stable than the calculated $\mathrm{BF}\left({ }^{1} \Sigma^{+}\right)$ BDE. Our calculated $\mathrm{F}_{2} \mathrm{~B}-\mathrm{F}$ BDE is in excellent agreement

with the experimental value derived from a mass spectrometry study ${ }^{52}$ but differs by $20 \mathrm{kcal} / \mathrm{mol}$ from the other available experimental values, ${ }^{57,6}$ because of errors in the experimental $\Delta H_{\mathrm{f}}\left(\mathrm{BF}_{2}\right)$. The $\mathrm{F}_{2} \mathrm{~B}-\mathrm{F}$ BDE is $9.6 \mathrm{kcal} / \mathrm{mol}$ less than the BDE of $\mathrm{BF}\left({ }^{1} \Sigma^{+}\right)$. The strong bond is consistent with back-bonding from the F lone pairs to the vacant B out-of-plane p orbital. ${ }^{58}$ Our calculated value is in good agreement with previous calculations. ${ }^{22,24}$ The $\mathrm{Cl}_{2} \mathrm{~B}-\mathrm{Cl} \mathrm{BDE}$ is calculated to be 12 and $8 \mathrm{kcal} / \mathrm{mol}$ larger, respectively, than the reported experimental values ${ }^{6,57}$ and $3.1 \mathrm{kcal} / \mathrm{mol}$ less than the BDE of $\mathrm{BCl}\left({ }^{1} \Sigma^{+}\right)$. Our calculated value is within $0.6 \mathrm{kcal} / \mathrm{mol}$ of a previously reported $\operatorname{CCSD}(\mathrm{T}) / \mathrm{CBS}$ value. ${ }^{22}$ The $\mathrm{Br}_{2} \mathrm{~B}-\mathrm{Br}$
and $\mathrm{I}_{2} \mathrm{~B}-\mathrm{I}$ BDEs are calculated to be 8.6 and $10.8 \mathrm{kcal} / \mathrm{mol}$ larger than the JANAF values ${ }^{6}$ and only 2.6 and $1.2 \mathrm{kcal} /$ mol smaller than the $\mathrm{BBr}\left({ }^{1} \Sigma^{+}\right)$and $\mathrm{BI}\left({ }^{1} \Sigma^{+}\right)$BDEs, respectively, showing that the other halide substituents have only a small effect on the $\mathrm{B}-\mathrm{X}$ BDE. The $\mathrm{I}_{2} \mathrm{~B}-\mathrm{I} \mathrm{BDE}$ is predicted to be $93 \mathrm{kcal} / \mathrm{mol}$ smaller than the $\mathrm{F}_{2} \mathrm{~B}-\mathrm{F}$ BDE. For the Group VIIA substituents, there is the expected decrease in $\mathrm{X}_{2} \mathrm{~B}-\mathrm{X} \operatorname{BDE}$ as one increases the atomic number.

The second highest $\mathrm{B}-\mathrm{X} \operatorname{BDE}$ of the $\mathrm{BX}_{3}$ compounds is predicted for the hydroxyl substituent, which is isoelectronic with fluorine. The $(\mathrm{HO})_{2} \mathrm{~B}-\mathrm{OH} \mathrm{BDE}$ is $15.7 \mathrm{kcal} / \mathrm{mol}$ larger than the JANAF value. ${ }^{6}$ The $(\mathrm{HO})_{2} \mathrm{~B}-\mathrm{OH} \mathrm{BDE}$ is $7.4 \mathrm{kcal} /$

${ }^{a}$ Reference 57. ${ }^{b}$ Reference 6. ${ }^{c}$ Reference 52. ${ }^{d}$ Reference 22. ${ }^{e}$ Reference 24. ${ }^{f}$ Reference 48. ${ }^{g}$ Reference 4. ${ }^{h}$ Reference 21. ${ }^{i}$ Reference 53. ${ }^{j}$ Reference 54. ${ }^{k}$ Reference 56. ${ }^{l}$ Reference 7. ${ }^{m}$ Reference 8. ${ }^{n}$ Reference 9.
mol less than the $\mathrm{B}-\mathrm{OH} \mathrm{BDE}$ and $23 \mathrm{kcal} / \mathrm{mol}$ less than the $\mathrm{F}_{2} \mathrm{~B}-\mathrm{F}$ BDE. The $\left(\mathrm{H}_{2} \mathrm{~N}\right)_{2} \mathrm{~B}-\mathrm{NH}_{2}$ and $(\mathrm{HS})_{2} \mathrm{~B}-\mathrm{SH}$ BDEs are predicted to be $4 \mathrm{kcal} / \mathrm{mol}$ lower and $6 \mathrm{kcal} / \mathrm{mol}$ higher than the $\mathrm{B}-\mathrm{NH}_{2}$ and $\mathrm{B}-\mathrm{SH}$ BDEs, respectively, and 47 and $71 \mathrm{kcal} /$ mol lower, respectively, than the $\mathrm{F}_{2} \mathrm{~B}-\mathrm{F}$ BDE.

Similar trends were found in the $\mathrm{HBX}-\mathrm{X} \mathrm{BDE}^{\text {of }}$ the $\mathrm{HBX}_{2}$ molecules. Substitution of H for X to form $\mathrm{HBX}_{2}$ leads to an average increase of $3 \mathrm{kcal} / \mathrm{mol}$ in the HBX-X BDE of the $\mathrm{HBX}_{2}$ molecules relative to the $\mathrm{BX}_{3}$ molecules. The HBF-F BDE is again the largest $\mathrm{HBX}-\mathrm{X} \mathrm{BDE}$ and is calculated to be slightly larger than the $\mathrm{F}_{2} \mathrm{~B}-\mathrm{F}$ BDE and $7.4 \mathrm{kcal} / \mathrm{mol}$ less than the BDE in BF $\left({ }^{1} \Sigma^{+}\right)$. The G-2 and CBS-4 values are in good agreement with our calculated value for the HBF-F BDE. ${ }^{24}$ The $\mathrm{HBCl}-\mathrm{Cl}$ and $\mathrm{HBBr}-\mathrm{Br}$ BDEs are calculated to be $1 \mathrm{kcal} /$ mol more stable than the corresponding diatomic BDEs. There is a decrease in the $\mathrm{HBX}-\mathrm{X}$ BDE with halide substitution, with the HBI-I BDE predicted to be the lowest, $91 \mathrm{kcal} / \mathrm{mol}$ less than the HBF-F BDE. The HBI-I BDE is 4 and $3 \mathrm{kcal} / \mathrm{mol}$ more stable than the first $\mathrm{B}-\mathrm{I} \mathrm{BDE}$ in $\mathrm{BI}_{3}$ and $\mathrm{BI}\left({ }^{1} \Sigma^{+}\right)$, respectively.

The $\mathrm{HB}(\mathrm{OH})-\mathrm{OH} \mathrm{BDE}$ is calculated to be slightly higher than the $(\mathrm{HO})_{2} \mathrm{~B}-\mathrm{OH} \mathrm{BDE}, 7 \mathrm{kcal} / \mathrm{mol}$ less than the $\mathrm{B}-\mathrm{OH}$ BDE , and $24 \mathrm{kcal} / \mathrm{mol}$ less than the $\mathrm{HBF}-\mathrm{F}$ BDE. The $\mathrm{HB}\left(\mathrm{NH}_{2}\right)-\mathrm{NH}_{2}$ and $\mathrm{HB}(\mathrm{SH})-\mathrm{SH}$ BDEs are predicted to be 4 $\mathrm{kcal} / \mathrm{mol}$ larger than the analogous first BDE in $\mathrm{B}\left(\mathrm{NH}_{2}\right)_{3}$ and $\mathrm{B}(\mathrm{SH})_{3}$, respectively. The $\mathrm{HB}\left(\mathrm{NH}_{2}\right)-\mathrm{NH}_{2} \mathrm{BDE}$ is predicted to be approximately the same as the BDE in $\mathrm{B}-\mathrm{NH}_{2}$, while the $\mathrm{HB}(\mathrm{SH})-\mathrm{SH} \operatorname{BDE}$ is $10 \mathrm{kcal} / \mathrm{mol}$ larger than the $\mathrm{B}-\mathrm{SH}$ BDE. The $\mathrm{HB}\left(\mathrm{NH}_{2}\right)-\mathrm{NH}_{2}$ and $\mathrm{HB}(\mathrm{SH})-\mathrm{SH}$ BDEs are calculated to be 45 and $69 \mathrm{kcal} / \mathrm{mol}$ less than the $\mathrm{HBF}-\mathrm{FBDE}$, respectively.

The highest and lowest $\mathrm{B}-\mathrm{H}$ BDEs for the $\mathrm{HBX}_{2}$ compounds were calculated for $\mathrm{H}-\mathrm{BF}_{2}$ and $\mathrm{H}-\mathrm{BI}_{2}$, respectively, bracketing the $\mathrm{H}-\mathrm{BH}_{2} \mathrm{BDE}$ obtained from the calculated $\Delta H_{\mathrm{f}}\left(\mathrm{BH}_{3}\right)$ and $\Delta H_{\mathrm{f}}\left(\mathrm{BH}_{2}\right)$, indicating only a small substituent effect on the $\mathrm{B}-\mathrm{H}$ BDEs. Our calculated value for the $\mathrm{H}-\mathrm{BF}_{2} \mathrm{BDE}$ is in good agreement with the lower level G-2 and CBS-4 values. ${ }^{24}$ For all of the $\mathrm{HBX}_{2}$ molecules, the $\mathrm{HBX}-\mathrm{X} \mathrm{BDE}$ is larger than the $\mathrm{X}_{2} \mathrm{~B}-\mathrm{H}$ BDE, except in $\mathrm{HBBr}_{2}$ where the $\mathrm{Br}_{2} \mathrm{~B}-\mathrm{H}$ and $\mathrm{HBBr}-\mathrm{Br}$ BDEs are the same and in $\mathrm{HBI}_{2}$ where the $\mathrm{I}_{2} \mathrm{~B}-\mathrm{H}$ BDE is larger than the $\mathrm{HBI}-\mathrm{I} \mathrm{BDE}$ by $18 \mathrm{kcal} / \mathrm{mol}$.

The $\mathrm{B}-\mathrm{X}$ BDEs in the $\mathrm{H}_{2} \mathrm{BX}$ molecules were calculated using our revised $\Delta H_{\mathrm{f}}\left(\mathrm{BH}_{2}\right)^{45}$ with the new heat of formation of the $B$ atom. The substitution of a second H for X to form $\mathrm{H}_{2} \mathrm{BX}$ leads to an increase in the $\mathrm{H}_{2} \mathrm{~B}-\mathrm{X}$ BDE compared to the $\mathrm{HBX}-\mathrm{X} \operatorname{BDE}$ except for $\mathrm{X}=\mathrm{F}$, where a decrease of $4 \mathrm{kcal} /$ mol is predicted for the $\mathrm{H}_{2} \mathrm{~B}-\mathrm{F}$ BDE compared to the $\mathrm{HBF}-\mathrm{F}$ BDE. There is also a general increase in the $\mathrm{H}_{2} \mathrm{~B}-\mathrm{X}$ BDE compared to the $\mathrm{B}-\mathrm{X} \operatorname{BDE}$ in the diatomic molecules except for $\mathrm{X}=\mathrm{F}$ and OH with a predicted decrease of 12 and $5 \mathrm{kcal} /$ mol in the $\mathrm{H}_{2} \mathrm{~B}-\mathrm{F}$ and $\mathrm{H}_{2} \mathrm{~B}-\mathrm{OH}$ BDEs compared to the analogous BDEs in $\mathrm{BF}\left({ }^{1} \Sigma^{+}\right)$and $\mathrm{B}(\mathrm{OH})$, respectively. The $\mathrm{H}_{2} \mathrm{~B}-\mathrm{F}$ BDE differs by $24 \mathrm{kcal} / \mathrm{mol}$ from the reported experimental value. The $\mathrm{H}_{2} \mathrm{~B}-\mathrm{F}$ BDE is the highest BDE predicted for the $\mathrm{H}_{2} \mathrm{BX}$ molecules, and similar trends are noted as found for the BDEs of $\mathrm{BX}_{3}$ and $\mathrm{HBX}_{2}$. Our calculated value for the $\mathrm{H}_{2} \mathrm{~B}-\mathrm{F}$ BDE is in good agreement with the lower level G-2 and CBS-4 values. ${ }^{24}$ There is a general decrease in the $\mathrm{H}_{2} \mathrm{~B}-\mathrm{X}$ BDE down the group for the halide substituents, with that of iodine predicted to have the smallest $\mathrm{H}_{2} \mathrm{~B}-\mathrm{X} \mathrm{BDE}, 83 \mathrm{kcal} /$ mol less than the $\mathrm{H}_{2} \mathrm{~B}-\mathrm{F}$ BDE but $7 \mathrm{kcal} / \mathrm{mol}$ more stable than the BDE of BI $\left({ }^{1} \Sigma^{+}\right)$. The $\mathrm{H}_{2} \mathrm{~B}-\mathrm{NH}_{2}$ and $\mathrm{H}_{2} \mathrm{~B}-$ SH BDEs are calculated to be 29 and $58 \mathrm{kcal} / \mathrm{mol}$ smaller than the $\mathrm{H}_{2} \mathrm{~B}-\mathrm{F}$ BDE , respectively, and 12 and $17 \mathrm{kcal} / \mathrm{mol}$ larger than the corresponding BDEs in $\mathrm{B}\left(\mathrm{NH}_{2}\right)$ and $\mathrm{B}(\mathrm{SH})$, respectively.

As for the $\mathrm{HBX}_{2}$ compounds, the effect of the substituent on the first $\mathrm{B}-\mathrm{H}$ BDE in $\mathrm{H}_{2} \mathrm{BX}$ is small when compared to the first $\mathrm{B}-\mathrm{H} \operatorname{BDE}$ in $\mathrm{BH}_{3}$. The largest difference is predicted for the $\mathrm{HBI}-\mathrm{H} \mathrm{BDE}$, which is only $1.6 \mathrm{kcal} / \mathrm{mol}$ less than the $\mathrm{H}-\mathrm{BH}_{2} \mathrm{BDE}$. The $\mathrm{HBF}-\mathrm{H} \mathrm{BDE}$ has been calculated at the G-2 and CBS-4 levels, ${ }^{24}$ and show good agreement with our higher level $\operatorname{CCSD}(\mathrm{T}) / \mathrm{CBS}$ value. For the $\mathrm{H}_{2} \mathrm{BX}$ molecules, the $\mathrm{H}_{2} \mathrm{~B}-\mathrm{X}$ BDE is larger than the $\mathrm{HBX}-\mathrm{H}$ BDE except for $\mathrm{H}_{2} \mathrm{BI}$ where the $\mathrm{H}_{2} \mathrm{~B}-\mathrm{I}$ BDE is $17 \mathrm{kcal} / \mathrm{mol}$ less than the $\mathrm{HBI}-\mathrm{H}$ BDE.

We also predicted the $\mathrm{B}-\mathrm{X}$ and $\mathrm{B}-\mathrm{H}$ BDEs in the $\mathrm{BX}_{2}$ and HBX radicals. Although the $\mathrm{XB}-\mathrm{X}$ and $\mathrm{HB}-\mathrm{X}$ BDEs follow similar trends to those discussed above, there is a considerable decrease in the strength of both compared to the corresponding $\mathrm{X}_{2} \mathrm{~B}-\mathrm{X}, \mathrm{HBX}-\mathrm{X}, \mathrm{H}_{2} \mathrm{~B}-\mathrm{X}$, and $\mathrm{B}-\mathrm{X}$ BDEs. Our calculated $\mathrm{FB}-\mathrm{F}$ BDE is in excellent agreement with the experimental value derived from a mass spectrometry study of the $\mathrm{BF}_{2}$ radical, ${ }^{52}$ but differs from the other experimental values, ${ }^{3,6}$ due to errors in $\Delta H_{\mathrm{f}}\left(\mathrm{BF}_{2}\right)$. Our calculated value is in good agreement with other calculated values. ${ }^{22,24}$ The FB-F BDE is significantly lower than the $\operatorname{BDE}$ in $\operatorname{BF}\left({ }^{1} \Sigma^{+}\right)$by $70 \mathrm{kcal} / \mathrm{mol}$. The calculated $\mathrm{ClB}-\mathrm{Cl} \mathrm{BDE}$ is within $3.4 \mathrm{kcal} / \mathrm{mol}$ of one of the reported experimental value and $15 \mathrm{kcal} / \mathrm{mol}$ of the other reported value, ${ }^{3}$ and smaller than the $\mathrm{BCl}\left({ }^{1} \Sigma^{+}\right) \mathrm{BDE}$ by $43 \mathrm{kcal} / \mathrm{mol}$. Our calculated value is in excellent agreement with the reported $\operatorname{CCSD}(\mathrm{T}) / \mathrm{CBS}$ value. ${ }^{22}$ The $\mathrm{BrB}-\mathrm{Br}$ and IB-I BDEs differ by 5 and $7 \mathrm{kcal} / \mathrm{mol}$ from the reported experimental values, respectively, ${ }^{3}$ and are predicted to be 38 and $31 \mathrm{kcal} / \mathrm{mol}$ less stable than the analogous BDEs in $\mathrm{BBr}\left({ }^{1} \Sigma^{+}\right)$and $\mathrm{BI}\left({ }^{1} \Sigma^{+}\right)$, respectively. Our calculated value for the $(\mathrm{HO}) \mathrm{B}-\mathrm{OH} \mathrm{BDE}$ is not in agreement with the reported experimental value. ${ }^{6}$

The first $\mathrm{B}-\mathrm{F}$ adiabatic BDEs of all the fluoroboranes are large except for $\mathrm{BF}_{2}$, which is much lower due to the relative instability of the $\mathrm{BF}_{2}$ radical and the stability of the closedshell singlet diatomic BF . The adiabatic $\mathrm{B}-\mathrm{F}$ BDE for ${ }^{2} \mathrm{BF}_{2}$ produces $\mathrm{BF}\left({ }^{1} \Sigma^{+}\right)$and $\mathrm{F}\left({ }^{2} \mathrm{P}\right)$. Following our previous study on the BDEs in the $\mathrm{PF}_{x} \mathrm{O}_{y}$ and $\mathrm{SF}_{x} \mathrm{O}_{y}$ compounds, ${ }^{2}$ in order to compare the BDEs, it may be more appropriate to consider the diabatic BDE with the formation of ${ }^{3} \mathrm{BF}$ where there are two unpaired electrons: one from the unpaired electron on $\mathrm{BF}_{2}$ and one from the $\mathrm{B}-\mathrm{F}$ bond that was broken. Inclusion of the singlet-triplet splitting for BF obtained at the CCSD(T)/CBS// MP2/aVTZ level (Supporting Information, Table SM-8) provides an estimate of the reorganization energy. We then obtain a diabatic BDE of $193.4 \mathrm{kcal} / \mathrm{mol}$, which is more consistent with the other $\mathrm{B}-\mathrm{F}$ BDEs, 23 and $14 \mathrm{kcal} / \mathrm{mol}$ larger than the first $\mathrm{B}-\mathrm{F} \quad \mathrm{BDE}$ in $\mathrm{BF}_{3}$ and $\mathrm{BF}\left({ }^{1} \Sigma^{+}\right)$, respectively. The reorganization energy in this case is the pairing of the two electrons to form the lone pair on BF to give the singlet structure. Our calculated diabatic $\mathrm{BF}-\mathrm{F}$ BDE is in good agreement with the G-2 and CBS-4 diabatic BF-F BDEs of 195.5 and 193.2 $\mathrm{kcal} / \mathrm{mol}$, respectively. ${ }^{24}$ For the other molecules, we can also consider dissociation to the diabatic limit given by the reaction ${ }^{2} \mathrm{BX}_{2} \rightarrow{ }^{3} \mathrm{BX}+{ }^{2} \mathrm{X}$. We calculated the singlet-triplet splitting for the BX molecules at the $\operatorname{CCSD}(\mathrm{T}) / \mathrm{CBS} / / \mathrm{MP} 2 / \mathrm{aVTZ}$ level (Supporting Information, Table SM-8). Use of the singlet-triplet splitting in the BX molecules leads to diabatic BX - X BDEs of $136.3,116.1,94.5,137.0,165.7$, and $109.5 \mathrm{kcal} / \mathrm{mol}$ for X $=\mathrm{Cl}, \mathrm{Br}, \mathrm{I}, \mathrm{NH}_{2}, \mathrm{OH}$, and SH , respectively. These values are comparable and on average about $16 \mathrm{kcal} / \mathrm{mol}$ larger than the corresponding first $\mathrm{B}-\mathrm{X} \mathrm{BDE}$ in $\mathrm{BX}_{3}$.

The HB-F BDE is the largest for the HBX molecules and is in excellent agreement with the reported experimental ${ }^{48}$ and G-2 and CBS-4 theoretical values. ${ }^{24}$ The B-X BDE decreases down
the group, and the $\mathrm{HB}-\mathrm{I} \mathrm{BDE}$ is calculated to be $82 \mathrm{kcal} / \mathrm{mol}$ smaller than the $\mathrm{HB}-\mathrm{F}$ BDE. The $\mathrm{HB}-\mathrm{X}$ BDEs where $\mathrm{X}=$ $\mathrm{OH}, \mathrm{NH}_{2}$, and SH are calculated to be 18,30 , and $57 \mathrm{kcal} / \mathrm{mol}$ smaller than the $\mathrm{HB}-\mathrm{F}$ BDE, respectively.

The $\mathrm{HB}-\mathrm{F}$ BDE is 24 and $36 \mathrm{kcal} / \mathrm{mol}$ smaller than the $\mathrm{H}_{2} \mathrm{~B}-\mathrm{F}$ and $\mathrm{B}-\mathrm{F}$ BDEs, respectively. Again, it is appropriate to consider dissociation of the products to the diabatic limit. We define the diabatic $\mathrm{B}-\mathrm{F}$ BDE in HBF as occurring with dissociation to the excited ${ }^{3} \Pi$ state of BH , which has two unpaired electrons: one from the unpaired electron on HBF and one from the $\mathrm{B}-\mathrm{F}$ bond that was broken. The experimental singlet-triplet splitting of the BH radical is $10410 \mathrm{~cm}^{-1}$ (29.7 $\mathrm{kcal} / \mathrm{mol}){ }^{59}$ giving a diabatic $\mathrm{B}-\mathrm{F} \mathrm{BDE}$ in HBF of $173.9 \mathrm{kcal} /$ mol, consistent with the predicted $\mathrm{B}-\mathrm{F}$ BDEs in $\mathrm{BF}_{3}, \mathrm{HBF}_{2}$, $\mathrm{H}_{2} \mathrm{BF}$, and BF . The $\mathrm{HB}-\mathrm{F}$ diabatic BDE has been calculated at the G-2 and CBS-4 levels, and the results are in good agreement with our $\operatorname{CCSD}(\mathrm{T}) / \mathrm{CBS}$ value. ${ }^{24}$ We predict the $\mathrm{HB}-\mathrm{X}$ diabatic BDEs for $\mathrm{X}=\mathrm{Cl}, \mathrm{Br}, \mathrm{I}, \mathrm{NH}_{2}, \mathrm{OH}$, and SH to be $129.0,111.6,92.3,143.6,156.4$, and $117.0 \mathrm{kcal} / \mathrm{mol}$. These diabatic $\mathrm{HB}-\mathrm{X}$ BDEs are on average $6 \mathrm{kcal} / \mathrm{mol}$ larger than the analogous $\mathrm{H}_{2} \mathrm{~B}-\mathrm{X}$ BDE.

The corresponding $\mathrm{B}-\mathrm{H}$ BDEs of the HBX molecules are also considerably less than the $\mathrm{B}-\mathrm{H} \operatorname{BDE}$ in $\mathrm{BH}_{3}$. The smallest $\mathrm{H}-\mathrm{BX} \mathrm{BDE}$ is predicted for $\mathrm{H}-\mathrm{BF}, 58 \mathrm{kcal} / \mathrm{mol}$ less than the $\mathrm{H}-\mathrm{BH}_{2} \mathrm{BDE}$. Our calculated value of the $\mathrm{H}-\mathrm{BF} \mathrm{BDE}$ is in good agreement with the lower level G-2 and CBS-4 values. ${ }^{24}$ We consider dissociation to the diabatic asymptote defined by the reaction ${ }^{2} \mathrm{HBX} \rightarrow{ }^{3} \mathrm{BX}+{ }^{2} \mathrm{H}$. Use of the singlet-triplet splittings (Table SM-8) yields diabatic $\mathrm{B}-\mathrm{H}$ BDEs that are considerably larger than the $\mathrm{B}-\mathrm{H} \mathrm{BDE}$ in $\mathrm{BH}_{3}$ by as much as $26 \mathrm{kcal} / \mathrm{mol}$ in HBF, which suggests that use of this diabatic model may not be appropriate. Our calculated diabatic $\mathrm{H}-\mathrm{BF}$ BDE of $129.3 \mathrm{kcal} / \mathrm{mol}$ is in good agreement with the G-2 and CBS-4 values of 130.3 and $128.2 \mathrm{kcal} / \mathrm{mol}$, respectively. ${ }^{24}$ For $\mathrm{HB}(\mathrm{SH})$, we find the $\mathrm{B}-\mathrm{H}$ diabatic BDE to be only $5 \mathrm{kcal} / \mathrm{mol}$ larger than the $\mathrm{H}-\mathrm{BH}_{2} \mathrm{BDE}$. Comparison of the $\mathrm{B}-\mathrm{X}$ and $\mathrm{B}-\mathrm{H}$ BDEs in the HBX molecules shows that the $\mathrm{HB}-\mathrm{X}$ BDE is larger than the $\mathrm{XB}-\mathrm{H} B D E$, except for HBI where the $\mathrm{HB}-\mathrm{I}$ BDE is smaller than the $\mathrm{H}-\mathrm{BI}$ BDE by $6.1 \mathrm{kcal} / \mathrm{mol}$.

Regeneration of Spent Fuel from Ammonia Borane. On the basis of the BDEs, it is unlikely that $\mathrm{B}-\mathrm{X}$ to $\mathrm{B}-\mathrm{H}$ conversion will occur for any of the substituted $\mathrm{HBX}_{2}, \mathrm{H}_{2} \mathrm{BX}$, and HBX molecules studied. The iodine derivatives were the most favorable for $\mathrm{B}-\mathrm{X}$ to $\mathrm{B}-\mathrm{H}$ conversion as the $\mathrm{B}-\mathrm{H}$ BDEs in $\mathrm{HBI}_{2}, \mathrm{H}_{2} \mathrm{BI}$, and BHI were more stable than the corresponding $\mathrm{B}-\mathrm{I}$ BDEs, respectively, and the $\mathrm{B}-\mathrm{I} \mathrm{BDE}$ in $\mathrm{BI}_{3}$ was the smallest.

We can calculate the heats of reaction for the disproportionation step in proposed reprocessing schemes for the regeneration of ammonia borane. The results are in Table 5. The generic disproportionation reactions are

$$
\begin{gather*}
2 \mathrm{HBX}_{2} \rightarrow \mathrm{H}_{2} \mathrm{BX}+\mathrm{BX} 3  \tag{2}\\
\mathrm{H}_{2} \mathrm{BX}+\mathrm{HBX}_{2} \rightarrow \mathrm{BH}_{3}+\mathrm{BX}_{3}  \tag{3}\\
2 \mathrm{H}_{2} \mathrm{BX} \rightarrow \mathrm{BH}_{3}+\mathrm{HBX}_{2} \tag{4}
\end{gather*}
$$

The disproportionation reactions involving the halide and hydroxyl derivatives are all relatively close to thermoneutral. Reaction 4, involving the F substituent, was the only exothermic reaction. These are model reactions for these processes, and $\mathrm{BH}_{3}$ and $\mathrm{BH}_{2} \mathrm{Cl}$ may form dimers in an actual system depending on the temperature. For example, Christe demonstrated the chemical transformation of $\mathrm{B}_{2} \mathrm{H}_{5} \mathrm{Cl}$ to $\mathrm{B}_{2} \mathrm{H}_{6}$ and $\mathrm{BCl}_{3}\left(6 \mathrm{~B}_{2} \mathrm{H}_{5} \mathrm{Cl} \leftrightarrow 5 \mathrm{~B}_{2} \mathrm{H}_{6}\right.$ $+2 \mathrm{BCl}_{3}$ ) in the gas phase using a platinum catalyst at

temperatures between 200 and $520{ }^{\circ} \mathrm{C} .{ }^{60}$ Another group has reported similar transformations for boron trihalides over Group IB metals at even higher temperatures, $550-750{ }^{\circ} \mathrm{C} .{ }^{61}$

We can predict the thermodynamics for the digestion reaction of borazine with the halide acids at 298 K in $\mathrm{kcal} / \mathrm{mol}$ given the recalculated heat of formation of borazine ${ }^{46}$ (using the new value for the heat of formation of the boron atom) of -118.8 $\mathrm{kcal} / \mathrm{mol}$ at 298 K in the gas phase. The reactions with $\mathrm{NH}_{3},{ }^{44}$ $\mathrm{H}_{2} \mathrm{O},{ }^{6}$ and $\mathrm{SH}_{2}{ }^{6}$ are also given for comparison.

$$
\begin{array}{cc}
\mathrm{c}-(\mathrm{BHNH})_{3}+6 \mathrm{HF} \rightarrow 3 \mathrm{NH}_{3}+3 \mathrm{HBF}_{2} & \Delta H=-56.3 \\
\mathrm{c}-(\mathrm{BHNH})_{3}+6 \mathrm{HCl} \rightarrow 3 \mathrm{NH}_{3}+3 \mathrm{HBCl}_{2} & \Delta H=35.6 \\
\mathrm{c}-(\mathrm{BHNH})_{3}+6 \mathrm{HBr} \rightarrow 3 \mathrm{NH}_{3}+3 \mathrm{HBBr}_{2} & \Delta H=51.2 \\
\mathrm{c}-(\mathrm{BHNH})_{3}+6 \mathrm{HI} \rightarrow 3 \mathrm{NH}_{3}+3 \mathrm{HBI}_{2} & \Delta H=71.7 \\
\mathrm{c}-(\mathrm{BHNH})_{3}+6 \mathrm{NH}_{3} \rightarrow 3 \mathrm{NH}_{3}+3 \mathrm{HB}\left(\mathrm{NH}_{2}\right)_{2} & \Delta H=-0.2 \tag{9}
\end{array}
$$

$\mathrm{c}-(\mathrm{BHNH})_{3}+6 \mathrm{H}_{2} \mathrm{O} \rightarrow 3 \mathrm{NH}_{3}+3 \mathrm{HB}(\mathrm{OH})_{2} \quad \Delta H=-35.4$

$$
\begin{equation*}
\mathrm{c}-(\mathrm{BHNH})_{3}+6 \mathrm{SH}_{2} \rightarrow 3 \mathrm{NH}_{3}+3 \mathrm{HB}(\mathrm{SH})_{2} \quad \Delta H=43.5 \tag{10}
\end{equation*}
$$

We predict the reaction of borazine with hydrofluoric acid to be considerably more exothermic as compared to the other halide acids. In order to better understand the digestion chemistry and the energetics for the borazine reactions, one can compare the various bond energies for the respective halide acid reactants and the $\mathrm{HBX}_{2}$ products. Breaking an HF bond compared to an HCl bond is more endothermic by $33 \mathrm{kcal} / \mathrm{mol}$; however, much of this energy difference in the $\mathrm{HF} / \mathrm{BF}_{3}$ system is gained back on forming $\mathrm{HBF}_{2}$. More notably, there is a difference of 96 $\mathrm{kcal} / \mathrm{mol}$ in the cumulative reaction sequence $\mathrm{BH}+\mathrm{X} \rightarrow \mathrm{HBX}$ $+\mathrm{X} \rightarrow \mathrm{HBX}_{2}$ between $\mathrm{X}=\mathrm{F}$ and $\mathrm{X}=\mathrm{Cl}$. Similarly, breaking an HBr bond is about $49 \mathrm{kcal} / \mathrm{mol}$ less endothermic than
breaking an HF bond; however, the cumulative reaction to form $\mathrm{HBBr}_{2}\left(\mathrm{BH}+\mathrm{Br} \rightarrow \mathrm{HBBr}+\mathrm{Br} \rightarrow \mathrm{HBBr}_{2}\right)$ is only exothermic by $184 \mathrm{kcal} / \mathrm{mol}$ as compared to $317 \mathrm{kcal} / \mathrm{mol}$ for the analagous fluorine reaction. Although breaking an HI bond is considerably less endothermic than breaking an HF bond by $66 \mathrm{kcal} / \mathrm{mol}$, only $144 \mathrm{kcal} / \mathrm{mol}$ is regained in forming $\mathrm{HBI}_{2}$, and this value is less than half the equivalent reaction for the fluoride derivatives. The digestion reaction involving $\mathrm{H}_{2} \mathrm{O}$ is also exothermic, but is $\sim 21 \mathrm{kcal} / \mathrm{mol}$ less compared to the reaction with HF. The reactions involving $\mathrm{NH}_{3}$ are thermoneutral, and the reactions involving $\mathrm{SH}_{2}$ are endothermic.

## Conclusions

The heats of formation at 0 and 298 K are predicted for a range of substituted borane compounds, $\mathrm{BX}_{3}, \mathrm{HBX}_{2}$, and $\mathrm{H}_{2} \mathrm{BX}$, and the radicals, $\mathrm{BX}_{2}$ and HBX , for $\mathrm{X}=\mathrm{F}, \mathrm{Cl}, \mathrm{Br}, \mathrm{I}, \mathrm{NH}_{2}, \mathrm{OH}$, and SH , on the basis of coupled cluster theory $(\operatorname{CCSD}(\mathrm{T}))$ calculations extrapolated to the complete basis set limit. The calculated values should be good to $\pm 1.5 \mathrm{kcal} / \mathrm{mol}$. The calculated heats of formation are in excellent agreement with the available experimental data for the closed-shell molecules, but show larger differences with the reported experimental values for the $\mathrm{BX}_{2}$ radicals. However, on the basis of extensive comparisons with experiment for a wide range of compounds, our calculated values for these radicals are to be preferred over the experimental values. Our calculated heats of formation allow us to predict the adiabatic BDEs for all of the compounds to within $\pm 1.5 \mathrm{kcal} / \mathrm{mol}$, dramatically improving the estimates of these important quantities, particularly for the radicals.

The calculated BDEs provide insight into the reactivity of these molecules. The $\mathrm{B}-\mathrm{F}$ BDE is the largest $\mathrm{B}-\mathrm{X}$ BDE predicted for $\mathrm{BX}_{2}, \mathrm{HBX}_{2}$, and $\mathrm{H}_{2} \mathrm{BX}$, and for the halogens, there is the expected decrease in $\mathrm{B}-\mathrm{X} \mathrm{BDE}$ with increasing atomic number. For ammonia borane spent fuel regeneration processes, $\mathrm{B}-\mathrm{X}$ to $\mathrm{B}-\mathrm{H}$ conversion will most likely not occur for any of the substituted $\mathrm{HBX}_{2}, \mathrm{H}_{2} \mathrm{BX}$, and HBX molecules studied, except for the iodine derivatives, which were the most favorable with the $\mathrm{B}-\mathrm{H}$ BDEs in $\mathrm{HBI}_{2}, \mathrm{H}_{2} \mathrm{BI}$, and HBI larger than the corresponding $\mathrm{B}-\mathrm{I}$ BDEs, respectively, and the $\mathrm{B}-\mathrm{I}$ BDE in $\mathrm{BI}_{3}$ being the lowest for all of the substituents studied.

Acknowledgment. We thank Prof. Karl Christe (USC) for helpful discussions and comments. Funding provided in part by the Department of Energy, Office of Energy Efficiency and Renewable Energy, under the Hydrogen Storage Grand Challenge, Solicitation No. DE-PS36-03GO93013. This work was done as part of the Chemical Hydrogen Storage Center. D.A.D. is indebted to the Robert Ramsay Endowment of the University of Alabama. Part of this work was performed at the W. R. Wiley Environmental Molecular Sciences Laboratory, a national scientific user facility sponsored by DOE's Office of Biological and Environmental Research and located at Pacific Northwest National Laboratory, operated for the DOE by Battelle.

Supporting Information Available: Geometry paramaters for $\mathrm{HX}(\mathrm{X}=\mathrm{F}, \mathrm{Cl}, \mathrm{Br}$, and I). Geometry parameters for BX , $\mathrm{HBX}, \mathrm{BX}_{2}$, and $\mathrm{H}_{3-n} \mathrm{BX}_{n}$ for ( $\mathrm{X}=\mathrm{F}, \mathrm{Cl}, \mathrm{Br}, \mathrm{I}, \mathrm{NH}_{2}, \mathrm{OH}$, and SH ) at the $\operatorname{CCSD}(\mathrm{T}) /$ aVDZ level. Total $\operatorname{CCSD}(\mathrm{T})$ energies as a function of basis set. Total CCSD(T)/aVnZ-PP energies as a function of basis set. Calculated MP2/aVTZ frequencies $\left(\mathrm{cm}^{-1}\right)$. Components for calculated atomization energies for HX ( $\mathrm{X}=$ $\mathrm{F}, \mathrm{Cl}, \mathrm{Br}$, and I). Components for calculated atomization energies for $\mathrm{BX}, \mathrm{HBX}, \mathrm{BX}_{2}$, and $\mathrm{H}_{3-n} \mathrm{BX}_{n}$ for $\mathrm{X}=\mathrm{Br}$ and I. Electronic contribution to the $\operatorname{CCSD}(\mathrm{T})$ singlet-triplet splitting for the

HBX compounds. $T_{1}$ diagnostics calculated at the $\operatorname{CCSD}(\mathrm{T}) /$ aVQZ level. This material is available free of charge via the Internet at http://pubs.acs.org.
