The crystal and molecular structure of *N*-nitro-*N*-methyl-*p*-nitroaniline was solved with good precision: $R = 0.058$ and average estimated standard deviation for bond lengths = $0.003 \text{ \AA}$. Analysis of the geometry reveals that the NO_2 attached to the N atom is strongly conjugated. Application of the HOSE model to its geometry and to geometries of 12 other *para*-substituted nitrobenzenes yields good linear regressions between canonical structure weights and Hammett σ values. by interpolation, σ for the N(Me)NO_2 group is estimated to 0.36.

INTRODUCTION

The *N*-methylnitramino group is a complex substituent for which substituent parameters such as σ constants¹ or group electronegativity^{2,3} are either not well established or not known. Undoubtedly the nitro group substituted at the nitrogen atom of the amino group increases its electronegativity. In addition, it should be taken into account that the lone pair at the amino group may be involved in cooperative interactions with the π -electron system of the nitro group. These kinds of interactions are usually reflected in the geometry of the molecule or that part of it involved in them.⁴

The aim of this work was to analyse similarities and dissimilarities in the geometry of the title system in comparison with the series of *para*-substituted derivatives of nitrobenzene and a few examples of *para*-substituted derivatives of aniline or its *N,N*-dialkyl derivatives.

EXPERIMENTAL

N-Nitro-*N*-methyl-*p*-nitroaniline (NMNA) was synthesized according to the literature procedure⁵ by nitration of *N*-methyl-*p*-nitroaniline with fuming nitric acid

($d = 1.52$) in acetic anhydride in 83% yield, m.p. $139\text{--}140^\circ \text{C}$ (from EtOH).

A crystal of dimensions $0.35 \times 0.3 \times 0.3 \text{ mm}$ was used for data collection. KM4 KUMA-Diffraction (a Polish diffractometer) was used with graphite monochromated $\text{Cu K}\alpha$ radiation. Unit cell parameters were obtained by a least-squares fit of the setting angles of 25 reflections in θ range $11 \leq \theta \leq 22^\circ$. The intensities of 1919 reflections were measured, with $\omega - 2\theta$ scans, index range $h \leq 10$, $k \leq 18$, $-20 \leq l \leq 20$, $\sin \theta/\lambda \leq 0.64 \text{ \AA}^{-1}$. The data were corrected for Lorentz and polarization effects but not for absorption. Three reflection (121, 321 and 332) were monitored every 100 reflections. No significant variation was detected (the variation of the intensity control reflections was $< 5\%$). Of 1919 measured reflections, 1382 with $F_0 \geq 3\sigma(F_0)$ were used in the calculations. The structure was solved by direct methods. Full-matrix least-squares refined minimizing $\sum w(|F_0| - |F_c|)^2$ with weights $w = [\sigma^2(F_0) + 0.00001(F_0)^2]^{-1}$ was employed. Final $R = 0.0582$, $wR = 0.0617$, $S = 5.2235$ for 1382 reflections and 146 parameters. The final difference Fourier map showed $\Delta\rho_{\text{max}} = +0.21$, $\Delta\rho_{\text{min}} = -0.23 \text{ e \AA}^{-3}$ and average $\Delta/\rho = 0.0008$. The computer programs SHELXS-86⁶ and SHELX-76⁷ were used. The final

geometrical calculations were performed with the CSU program.⁸ The molecular illustrations were drawn using PLUTO.⁹ Atomic scattering factors were taken from published tables.¹⁰

RESULTS AND DISCUSSION

The crystal data for NMNA are given in Table 1, final atomic parameters for heavy atoms are given in Table 2 and the molecular geometry and atom numbering are shown in Figure 1.

N(Me)NO₂ is almost perpendicular to the plane of the ring ($\varphi = -72.3^\circ$) whereas the other nitro group is almost coplanar with the ring ($\varphi = 2.5^\circ$).

^a *U*_{eq} is calculated as ¹¹ (U11^{*}(astar^{*}*a*)² + U22^{*}(bstar^{*}*b*)² + U33^{*}(cstar^{*}*c*)² + 2(U12^{*}astar^{*}bstar^{*}*a**b* cos gamma + U13^{*}astar^{*}cstar^{*}*a**c* cos beta + U23^{*}bstar^{*}cstar^{*}*b**c* cos alpha))/3, where astar, bstar and cstar are reciprocal *a*, *b* and *c*, respectively, and thermal parameters for anisotropic vibrations defined by Cruickshank¹² as $T = \exp(-2\pi^2(h^2U11^* + \dots + 2h^*k^*U12^* + \dots))$.

In order to determine the character of N(Me)NO₂ as a substituent, the appropriate bond lengths in NMNA, *p*-dinitrobenzene,¹³ *N,N,N',N'*-tetramethyl-*p*-phenylenediamine¹⁴ and *N,N*-diethyl-*p*-nitroaniline¹⁵ are compared in Table 3. Analysis of the differences in the lengths of the appropriate bonds leads to the conclusion that there is a strong similarity between NMNA and *p*-dinitrobenzene: no difference in the appropriate bond length in the ring exceeds 0.4 pm and the difference between the lengths of C₁N₁ is only 0.6 pm. This means that the nitro group interacts with the ring in NMNA almost as strongly as if it was linked directly to the ring. As the dihedral angle between the N(Me)NO₂ group and the ring is 72.3°, the interactions seem to be almost entirely a field/inductive effect.

Figure 1. Values of bond lengths, bond angles and dihedral angles between the best ring planes

Table 3. Comparison of bond lengths in NMNA, *p*-dinitrobenzene, *N,N,N',N'*-tetramethyl-phenylenediamine and *N,N* diethyl-*p*-nitroaniline

Compound	Ref.	Bond length (Å)				
		C ₄ N	C ₄ C ₃	C ₃ C ₂	C ₂ C ₁	C ₁ N
	This work	1.431	1.380	1.388	1.378	1.472
	13	1.478	1.376	1.387	1.376	1.478
	14	1.407	1.401	1.390	1.401	1.407
	15	1.433	1.386	1.366	1.420	1.354

Another problem is how the N(Me)NO₂ group in NMNA affects the ring bond lengths in comparison with other *p*-nitro-substituted benzene derivatives. It has already been shown¹⁶ that weights of the canonical structures in *p*-nitro-substituted derivatives of benzene follow the Hammett rule well. Here we applied the HOSE model¹⁷ to the geometry of NMNA and 12 *para*-substituted nitrobenzenes, taking into account the canonical structures presented in Figure 2. Values of the canonical structure weights are given in Table 4. Table 5 gives regression and correlation coefficients of the linear dependences

$$\%C(i) = \rho(i)\sigma(X) + \text{constant} \quad (1)$$

where $\sigma(X)$ represents Hammett substituent constants σ_p for electron-accepting substituents and σ_p^+ for electron-donating substituents (all the σ values used in this analysis were taken from Ref. 1, with the following values for σ : NEt₂ and NMe₂ -1.67, NH₂⁺ 0.57, NO₂ 0.81, NH₂ -1.47, NHMe -1.57; mean value between σ^+ for NMe₂ and NH₂, COOH 0.44, COO⁻ -0.05, Ph -0.21, -O⁻ -2.3, OH -0.91, OMe -0.79; $\rho(i)$ is the slope of equation (1), being a measure of the sensitivity of the weight of the *i*th canonical structure, $C(i)$, on the electron accepting/donating property of the substituent X.

Application of the appropriate canonical structure weights ($i = \text{I} + \text{II}$, V and VI) and those calculated for NMNA from experimental bond lengths in equation (1) gives, by interpolation, an average value of $\sigma = 0.36$. In view of the above discussion it follows that $\sigma_p(\text{NMeNO}_2) = \sigma_{\text{ind}}(\text{NMeNO}_2)$. Charton²⁸ gives a value of 0.39 for σ_{ind} , which is in good agreement with our σ_p value.
