#### Abstract

The Griffiths inequalities for Ising spin-glass models with Gaussian randomness of non-vanishing mean are proved using properties of the Gaussian distribution and gauge symmetry of the system. These inequalities imply that correlation functions are non-negative and monotonic along the Nishimori line in the phase diagram. From this result, the existence of thermodynamic limit for correlation functions and pressure is proved under free and fixed boundary conditions. Relations between the location of multicritical points are also derived for different lattices.

## 1. Introduction

Two Griffiths inequalities provide a significant insight into the phase transitions in ferromagnetic Ising models [1]. One of their formulations states that if the sets of Ising spins $S_{A}=\prod_{i \in A} S_{i}$ are coupled by an energy $-J_{A} S_{A}$ (for some positive $J_{A}$ ), the free energy $F$ and all the correlations are monotonic functions of the strength of any interactions $J$, namely:

$$
\begin{align*}
& -\frac{\mathrm{d}}{\mathrm{~d} J_{A}} F \geqslant 0  \tag{1}\\
& \frac{\mathrm{~d}}{\mathrm{~d} J_{B}}\left\langle S_{A}\right\rangle \geqslant 0 . \tag{2}
\end{align*}
$$

These inequalities can be used in ferromagnetic Ising models to prove that the free energy and correlation functions have the thermodynamic limit under several boundary conditions and to demonstrate the existence of phase transitions for various lattices. The proof of equations (1) and (2) [2] assumes that all the interactions among spins are ferromagnetic, a condition that clearly fails in spin-glass models which have both ferromagnetic and antiferromagnetic interactions.

Attempts to extend even only partially those or similar inequalities to the spin glasses have been unsuccessful until very recently after the technique of integration by parts has been powerfully exploited in the mathematically rigorous approaches: in [3, 4] the main results are based on correlation inequalities that represent the equivalent of the first Griffiths inequality (1) for the Sherrington-Kirkpatrick model and the Edwards-Anderson model, respectively. The monotonicity properties in $[3,4]$ are proved not with respect to the strength of the interaction but with respect to the variance of the random interaction.

In this letter, we show that a Gaussian Ising spin-glass model does fulfil the first and the second Griffiths inequalities (1) and (2) with respect to the mean of the distribution: pressure and correlations are monotonic functions with respect to the mean. The results are proved on the Nishimori line (NL), a restricted space of the phase diagram in which several exact results follow from the gauge symmetries of the system $[6,7]$.

We apply the resulting inequalities to prove the existence of the thermodynamic limit for the pressure and correlation functions under free and fixed boundary conditions. Moreover, we derive inequalities on the location of multicritical points.

In the next section, we present our results and their proofs. The applications of the inequalities are discussed in the last section. Some of the details of calculations are described in the appendix.

## 2. Inequalities

Let us consider a finite box $\Omega$, subset of a regular lattice $\mathcal{L}$. To each point $i \in \Omega$ we associate an Ising spin ( $S_{i}= \pm 1$ ) and denote their products by

$$
\begin{equation*}
S_{A}=\prod_{i \in A} S_{i} \tag{3}
\end{equation*}
$$

We consider the spin-glass model defined by the random potential

$$
\begin{equation*}
U_{\Omega}=\sum_{A \subset \Omega} \beta_{A} J_{A} S_{A} \tag{4}
\end{equation*}
$$

where $\beta_{A} \geqslant 0$ is the inverse of local temperature of subset $A$ and $J_{A}$ is a quenched random variable which follows the Gaussian distribution with positive mean $\left[J_{A}\right]=J_{A 0}$ and variance $\left[\left(J_{A}-J_{A 0}\right)^{2}\right]=\sigma_{A}^{2}$. The pressure function is defined as

$$
\begin{equation*}
P=\left[\log \sum_{S} \mathrm{e}^{U_{\Omega}}\right] \tag{5}
\end{equation*}
$$

from which all physical quantities can be derived.
The NL is defined in terms of the parameters $x_{A} \geqslant 0($ for all $A)$ as $[6,7]$

$$
\begin{equation*}
\beta_{A}=\frac{x_{A}}{\sigma_{A}} \quad J_{A 0}=\sigma_{A} x_{A} . \tag{6}
\end{equation*}
$$

Our results are the following inequalities:

$$
\begin{align*}
& \frac{\mathrm{d} P}{\mathrm{~d} x_{B}}=x_{B}\left[\left\langle S_{B}+1\right\rangle\right] \geqslant 0  \tag{7}\\
& \frac{\mathrm{~d}}{\mathrm{~d} x_{B}}\left[\left\langle S_{C}\right\rangle\right]=2 x_{B}\left[\left(\left\langle S_{B} S_{C}\right\rangle-\left\langle S_{B}\right\rangle\left\langle S_{C}\right\rangle\right)^{2}\right] \geqslant 0 . \tag{8}
\end{align*}
$$

Both inequalities hold for arbitrary subsets $B, C$ as long as the parameters satisfy NL condition (6).

The first and second inequalities are proved using some properties of the Gaussian distribution and the gauge theory. To prove the first inequality (7), we observe that on the NL the formula of the total derivative gives

$$
\begin{equation*}
\frac{\mathrm{d} P}{\mathrm{~d} x_{B}}=\frac{\partial P}{\partial \beta_{B}} \frac{\mathrm{~d} \beta_{B}}{\mathrm{~d} x_{B}}+\frac{\partial P}{\partial J_{B 0}} \frac{\mathrm{~d} J_{B 0}}{\mathrm{~d} x_{B}}=\left.\frac{1}{\sigma_{B}} \frac{\partial P}{\partial \beta_{B}}\right|_{\mathrm{NL}}+\left.\sigma_{B} \frac{\partial P}{\partial J_{B 0}}\right|_{\mathrm{NL}} . \tag{9}
\end{equation*}
$$

As shown in the appendix, we can derive the following identities from the properties of the Gaussian distribution for any operator $O$ :

$$
\begin{align*}
& {\left[J_{B} O\right]=J_{B 0}[O]+\sigma_{B}^{2}\left[\frac{\partial O}{\partial J_{B}}\right]}  \tag{10}\\
& \frac{\partial}{\partial J_{B 0}}[O]=\left[\frac{\partial O}{\partial J_{B}}\right] . \tag{11}
\end{align*}
$$

Note that both equations (10) and (11) are valid on and away from the NL. The identity (11) yields

$$
\begin{equation*}
\frac{\partial P}{\partial J_{B 0}}=\beta_{B}\left[\left\langle S_{B}\right\rangle\right] \tag{12}
\end{equation*}
$$

and a direct computation provides

$$
\begin{equation*}
\frac{\partial P}{\partial \beta_{B}}=\left[J_{B}\left\langle S_{B}\right\rangle\right] . \tag{13}
\end{equation*}
$$

Using the gauge theory we have on the $\mathrm{NL}[6,7]$

$$
\begin{equation*}
\left[\left\langle J_{B} S_{B}\right\rangle\right]=J_{B 0}=\sigma_{B} x_{B} \tag{14}
\end{equation*}
$$

From equations (9), (12)-(14), we immediately find equation (7).
It is also possible to obtain a related inequality, an explicit bound for the correlation function, as

$$
\begin{equation*}
\left[\left\langle S_{B}\right\rangle\right] \geqslant \frac{x_{B}^{2}}{1+x_{B}^{2}} \quad(B \in\{A\}) \quad\left[\left\langle S_{B}\right\rangle\right] \geqslant 0 \quad(B \notin\{A\}) \tag{15}
\end{equation*}
$$

For this purpose we observe that, when $B \in\{A\}$,

$$
\begin{equation*}
\left[\left\langle J_{B} S_{B}\right\rangle\right]=\int \prod_{A \subset \Omega} \mathrm{~d} J_{A}\left(\sqrt{P_{A}\left(J_{A}\right)} J_{B}\right)\left(\sqrt{P_{A}\left(J_{A}\right)}\left\langle S_{B}\right\rangle\right) \tag{16}
\end{equation*}
$$

Let us square both sides of the above equation and apply the Cauchy-Schwarz inequality to obtain

$$
\begin{equation*}
\left[\left\langle J_{B} S_{B}\right\rangle\right]^{2} \leqslant\left(\sigma_{B}^{2}+J_{B 0}^{2}\right)\left[\left\langle S_{B}\right\rangle^{2}\right] . \tag{17}
\end{equation*}
$$

Since the gauge theory yields an identity $[6,7]$

$$
\begin{equation*}
\left[\left\langle S_{B}\right\rangle\right]=\left[\left\langle S_{B}\right\rangle^{2}\right] \tag{18}
\end{equation*}
$$

on the NL under certain boundary conditions (free, periodic or fixed (all spins up)), we obtain equation (15) from equations (14) and (17). When $B \notin\{A\}$, the inequality (15) is a direct consequence of the identity (18). We note that the Gaussian distribution is not essential for the proof of the above inequality (15).

The proof of the second inequality (8) is similarly carried out. Derivative by the parameter $x_{B}$ is expressed as in equation (9) by

$$
\begin{equation*}
\frac{\mathrm{d}}{\mathrm{~d} x_{B}}\left[\left\langle S_{C}\right\rangle\right]=\left.\frac{1}{\sigma_{B}} \frac{\partial}{\partial \beta_{B}}\left[\left\langle S_{C}\right\rangle\right]\right|_{\mathrm{NL}}+\left.\sigma_{B} \frac{\partial}{\partial J_{B 0}}\left[\left\langle S_{C}\right\rangle\right]\right|_{\mathrm{NL}} \tag{19}
\end{equation*}
$$

Derivative by $\beta_{B}$ is easily calculated as

$$
\begin{equation*}
\frac{\partial}{\partial \beta_{B}}\left[\left\langle S_{C}\right\rangle\right]=\left[J_{B}\left\langle S_{B} S_{C}\right\rangle\right]-\left[J_{B}\left\langle S_{B}\right\rangle\left\langle S_{C}\right\rangle\right] . \tag{20}
\end{equation*}
$$

Substitution of equation (10) into equation (20) yields
$\frac{1}{\sigma_{B}} \frac{\partial}{\partial \beta_{B}}\left[\left\langle S_{C}\right\rangle\right]=\frac{J_{B 0}}{\sigma_{B}}\left[\left\langle S_{B} S_{C}\right\rangle-\left\langle S_{B}\right\rangle\left\langle S_{C}\right\rangle\right]-2 \sigma_{B} \beta_{B}\left[\left\langle S_{B}\right\rangle\left\langle S_{B} S_{C}\right\rangle-\left\langle S_{B}\right\rangle^{2}\left\langle S_{C}\right\rangle\right]$
and the identity (11) gives

$$
\begin{equation*}
\sigma_{B} \frac{\partial}{\partial J_{B 0}}\left[\left\langle S_{C}\right\rangle\right]=\sigma_{B} \beta_{B}\left[\left\langle S_{B} S_{C}\right\rangle-\left\langle S_{B}\right\rangle\left\langle S_{C}\right\rangle\right] . \tag{22}
\end{equation*}
$$

From equation (19) we obtain

$$
\begin{equation*}
\frac{\mathrm{d}}{\mathrm{~d} x_{B}}\left[\left\langle S_{C}\right\rangle\right]=2 x_{B}\left[\left\langle S_{B} S_{C}\right\rangle-\left\langle S_{B}\right\rangle\left\langle S_{C}\right\rangle-\left\langle S_{B}\right\rangle\left\langle S_{B} S_{C}\right\rangle+\left\langle S_{B}\right\rangle^{2}\left\langle S_{C}\right\rangle\right] . \tag{23}
\end{equation*}
$$

The gauge theory yields the following identities on the NL under the same boundary conditions as the identity (18) $[6,7]$ :

$$
\begin{align*}
& {\left[\left\langle S_{B} S_{C}\right\rangle\right]=\left[\left\langle S_{B} S_{C}\right\rangle^{2}\right]} \\
& {\left[\left\langle S_{B}\right\rangle\left\langle S_{C}\right\rangle\right]=\left[\left\langle S_{B}\right\rangle\left\langle S_{B} S_{C}\right\rangle\right]=\left[\left\langle S_{B}\right\rangle\left\langle S_{C}\right\rangle\left\langle S_{B} S_{C}\right\rangle\right]}  \tag{24}\\
& {\left[\left\langle S_{B}\right\rangle^{2}\left\langle S_{C}\right\rangle\right]=\left[\left\langle S_{B}\right\rangle^{2}\left\langle S_{C}\right\rangle^{2}\right]}
\end{align*}
$$

Therefore, we obtain from equation (23)

$$
\begin{equation*}
\frac{\mathrm{d}}{\mathrm{~d} x_{B}}\left[\left\langle S_{C}\right\rangle\right]=2 x_{B}\left[\left(\left\langle S_{B} S_{C}\right\rangle-\left\langle S_{B}\right\rangle\left\langle S_{C}\right\rangle\right)^{2}\right] \geqslant 0 \tag{25}
\end{equation*}
$$

In general, the following relation is proved similarly:

$$
\begin{align*}
\frac{\mathrm{d}}{\mathrm{~d} x_{B}}\left[\left\langle S_{C}\right\rangle^{2 k-1}\right] & =\frac{\mathrm{d}}{\mathrm{~d} x_{B}}\left[\left\langle S_{C}\right\rangle^{2 k}\right] \\
& =2 k(2 k-1) x_{B}\left[\left\langle S_{B}\right\rangle^{2 k-2}\left(\left\langle S_{B} S_{C}\right\rangle-\left\langle S_{B}\right\rangle\left\langle S_{C}\right\rangle\right)^{2}\right] \geqslant 0 . \tag{26}
\end{align*}
$$

It is also possible to prove the concavity of the pressure from the derivative of equation (7), since the second derivative of the pressure is calculated as

$$
\frac{\mathrm{d}^{2} P}{\mathrm{~d} x_{B} \mathrm{~d} x_{C}}= \begin{cases}x_{B} \frac{\mathrm{~d}}{\mathrm{~d} x_{C}}\left[\left\langle S_{B}\right\rangle\right] \geqslant 0 & (B \neq C)  \tag{27}\\ {\left[\left\langle S_{B}\right\rangle\right]+1+x_{B} \frac{\mathrm{~d}}{\mathrm{~d} x_{B}}\left[\left\langle S_{B}\right\rangle\right] \geqslant 0} & (B=C)\end{cases}
$$

where we use equations (8) and (15).

## 3. Discussions on physical consequences

The inequality (15) implies that a correlation function $\left[\left\langle S_{B}\right\rangle\right]$ is non-negative and increases towards unity when the parameter $x_{B}$ of the corresponding subset $B$ tends to infinity. This result is reasonable: for large $x_{B}$, the interaction $J_{B}$ is almost ferromagnetic and the local temperature is nearly zero, and therefore all the spins in the subset $B$ become parallel to each other.

An immediate result from the second inequality (8) is that an arbitrary $n$-point correlation function, including order parameters, is an increasing function of a parameter for any subset. In particular, a two-point correlation function increases with $x$ (which is proportional to the inverse temperature and the centre of distribution) and thus the correlation length becomes larger as $x$ increases, a natural result.

The two inequalities have profound consequences on the structure and existence of the thermodynamic limit $\Omega \nearrow \mathcal{L}$ for both pressure and correlation functions. The first inequality (7) tells us that the pressure is monotonically increasing with any $x_{A}$. Since on the NL the Boltzmann weight admits the representation

$$
\begin{equation*}
\mathrm{e}^{\sum_{A \in \Omega} x_{A} j_{A} S_{A}} \tag{28}
\end{equation*}
$$

where $j_{A}=J_{A} / \sigma_{A}$ is a Gaussian variable with mean $\left[j_{A}\right]=x_{A} \geqslant 0$ and variance $\left[\left(j_{A}-x_{A}\right)^{2}\right]=1$, the pressure can be expressed as

$$
\begin{equation*}
P=\left[\log \sum_{S} \mathrm{e}^{\sum_{A \in \Omega} x_{A} j_{A} S_{A}}\right] \tag{29}
\end{equation*}
$$

and the correlation as

$$
\begin{equation*}
\left[\left\langle S_{C}\right\rangle\right]=\left[\frac{\sum_{S} S_{C} \mathrm{e}^{\sum_{A \in \Omega} x_{A} j_{A} S_{A}}}{\sum_{S} \mathrm{e}^{\sum_{A \in \Omega} x_{A} j_{A} S_{A}}}\right] \tag{30}
\end{equation*}
$$

where both $P$ and $\left[\left\langle S_{C}\right\rangle\right]$ are functions only of $x$. From equation (29) we see that the $x_{A}$ tune the interaction of the set of spins $A$.

We can show the existence of the thermodynamic limit for the pressure per spin under a free boundary condition. Take a large cube $\Omega$ (consider for simplicity $d=2$ ) and cut it in four identical cubes $\Omega_{i}, i=1, \ldots, 4$. We can tune off the interactions among the cubes simply by setting all the $x$ among them equal to zero. In this case the total pressure is $P_{\Omega_{1}}+P_{\Omega_{2}}+P_{\Omega_{3}}+P_{\Omega_{4}}$. Then we can tune on the interactions from zero to their original value and the total pressure becomes $P_{\Omega}$. The monotonicity property (7) gives

$$
\begin{equation*}
P_{\Omega_{1}}+P_{\Omega_{2}}+P_{\Omega_{3}}+P_{\Omega_{4}} \leqslant P_{\Omega} \tag{31}
\end{equation*}
$$

which is the well-known sub-additivity property for the pressure and implies the existence of its density in the thermodynamic limit under two natural assumptions of invariance by translation of the Gaussian distributions and the stability boundedness [5].

Moreover the second inequality (8) can be used to prove the existence of the thermodynamic limit for the correlation functions in the same way as the first is used to prove the existence of the pressure. In fact, from equation (28), we see that when $x_{A}=0$ there is no interaction among the subset $A$, and to increase $x_{A}$ from zero is equivalent to adding an interaction to the subset $A$. From the second inequality (8), addition of an interaction for any subset increases all correlation functions.

This result can be used for the proof that correlation functions have a thermodynamic limit under free boundary conditions. Let us consider two finite sets $\Omega^{\prime} \subset \Omega$. The subset $\Omega$ is obtained from $\Omega^{\prime}$ by adding interactions. Then it is clear from the previous argument that

$$
\begin{equation*}
\left[\left\langle S_{B}\right\rangle\right]_{\Omega^{\prime}}^{(\mathrm{free})} \leqslant\left[\left\langle S_{B}\right\rangle\right]_{\Omega}^{(\mathrm{free})} . \tag{32}
\end{equation*}
$$

This implies that the correlation functions monotonically increase with the system size. Since correlation functions are bounded by unity, each of them tends to its unique limit as the volume of $\Omega$ tends to infinity. Therefore, the thermodynamic limit for correlation functions exists on the NL.

Monotonicity of the correlation functions with system size can also be proved under a fixed boundary condition. Fixed boundary conditions ( $S_{i}=+1$ for all boundary sites $i \in \partial \Omega$ ) are represented by applying very strong positive magnetic fields to all sites outside $\Omega$. This is equivalent to $x_{A} \rightarrow \infty$ for $A=\{i\}, i \in \partial \Omega$. Since the set $\Omega \supset \Omega^{\prime}$ is obtained from $\Omega^{\prime}$ by reducing magnetic fields for sites $i \in \Omega \backslash \Omega^{\prime}$, we have

$$
\begin{equation*}
\left[\left\langle S_{B}\right\rangle\right]_{\Omega^{\prime}}^{(\mathrm{fix})} \geqslant\left[\left\langle S_{B}\right\rangle\right]_{\Omega}^{(\mathrm{fix})} \tag{33}
\end{equation*}
$$

from the inequality (8). Because the inequality (15) yields lower bounds for $\left[\left\langle S_{B}\right\rangle\right]$, there should exist a well-defined limit as $\Omega \nearrow \mathcal{L}$. The thermodynamic limit of $\left[\left\langle S_{B}\right\rangle\right]^{(f i x)}$ may not necessarily be equal to that of $\left[\left\langle S_{B}\right\rangle\right]^{(\text {free) })}$, but the former cannot be less than the latter.

The second inequality can also be used for the argument about the location of the multicritical points, which are believed to lie on the NL [6, 7], for various lattices. For example, let us consider three two-dimensional lattices, the triangular (TR), square (SQ) and hexagonal (HEX) lattices. The triangular lattice is obtained from the square lattice with addition of bonds, and the square lattice is obtained from the hexagonal. Thus, the magnetizations of three lattices satisfy the following relation:

$$
\begin{equation*}
\left[\left\langle S_{i}\right\rangle\right]_{\mathrm{HEX}} \leqslant\left[\left\langle S_{i}\right\rangle\right]_{\mathrm{SQ}} \leqslant\left[\left\langle S_{i}\right\rangle\right]_{\mathrm{TR}} . \tag{34}
\end{equation*}
$$

Since the multicritical temperature is defined as

$$
\begin{equation*}
T_{\mathrm{c}}=\sup \left\{T ;\left[\left\langle S_{i}\right\rangle\right]>0\right\} \tag{35}
\end{equation*}
$$

we obtain

$$
\begin{equation*}
T_{\mathrm{c}}^{\mathrm{HEX}} \leqslant T_{\mathrm{c}}^{\mathrm{SQ}} \leqslant T_{\mathrm{c}}^{\mathrm{TR}} \tag{36}
\end{equation*}
$$

Similarly, the multicritical temperature of the simple cubic lattice is higher then that of the square lattice because the former lattice is constructed from the latter by adding interactions.

It is an interesting future problem to prove our results for other models, for example, the $\pm J$ Ising model, and to develop similar analyses away from the NL.

After submission of the manuscript we learnt that Kitatani [8] had discussed a related problem.

## Appendix

In this appendix, we derive equations (10) and (11) using some properties of the Gaussian distribution

$$
\begin{equation*}
P_{A}\left(J_{A}\right)=\frac{1}{\sqrt{2 \pi \sigma_{A}^{2}}} \exp \left(-\frac{\left(J_{A}-J_{A 0}\right)^{2}}{2 \sigma_{A}^{2}}\right) \tag{A.1}
\end{equation*}
$$

Let us consider the following quantity,

$$
\begin{equation*}
\left[\frac{\partial}{\partial J_{B}} O\left(\left\{J_{A}\right\}\right)\right]=\int \prod_{A \subset \Omega} \mathrm{~d} J_{A} P_{A}\left(J_{A}\right) \frac{\partial}{\partial J_{B}} O\left(\left\{J_{A}\right\}\right) \tag{A.2}
\end{equation*}
$$

where $O\left(\left\{J_{A}\right\}\right)$ is a function of interactions $\left\{J_{A}\right\}$. Since Gaussian distribution $P_{A}\left(J_{A}\right)$ decays rapidly as $\left|J_{A}\right| \rightarrow \infty$, we may rewrite the right-hand side using integration by parts as

$$
\begin{align*}
{\left[\frac{\partial}{\partial J_{B}} O\left(\left\{J_{A}\right\}\right)\right] } & =\int \prod_{\substack{A \subset \Omega \\
A \neq B}} \mathrm{~d} J_{A} P_{A}\left(J_{A}\right) \mathrm{d} J_{B} P_{B}\left(J_{B}\right) \frac{\partial}{\partial J_{B}} O\left(\left\{J_{A}\right\}\right)  \tag{A.3}\\
& =\int \prod_{\substack{A \subset \Omega \\
A \neq B}} \mathrm{~d} J_{A} P_{A}\left(J_{A}\right) \mathrm{d} J_{B}\left(-\frac{\partial}{\partial J_{B}} P_{B}\left(J_{B}\right)\right) O\left(\left\{J_{A}\right\}\right) . \tag{A.4}
\end{align*}
$$

Calculating the derivative of the Gaussian yields

$$
\begin{equation*}
\frac{\partial}{\partial J_{B}} P_{B}\left(J_{B}\right)=\frac{J_{B 0}-J_{B}}{\sigma_{B}^{2}} P_{B}\left(J_{B}\right) . \tag{A.5}
\end{equation*}
$$

This relation shows that

$$
\begin{align*}
{\left[\frac{\partial}{\partial J_{B}} O\left(\left\{J_{A}\right\}\right)\right] } & =\int \prod_{A \subset \Omega} \mathrm{~d} J_{A} P_{A}\left(J_{A}\right) \frac{J_{B}-J_{B 0}}{\sigma_{B}^{2}} O\left(\left\{J_{A}\right\}\right)  \tag{A.6}\\
& =\frac{1}{\sigma_{B}^{2}}\left\{\left[J_{B} O\left(\left\{J_{A}\right\}\right)\right]-J_{B 0}\left[O\left(\left\{J_{A}\right\}\right)\right]\right\} \tag{A.7}
\end{align*}
$$

which is equation (10).
For the proof of (11), we use the property that the Gaussian distribution $P_{B}\left(J_{B}\right)$ is a function of $J_{B}-J_{B 0}$,

$$
\begin{equation*}
\frac{\partial}{\partial J_{B}} P_{B}\left(J_{B}\right)=-\frac{\partial}{\partial J_{B 0}} P_{B}\left(J_{B}\right) . \tag{A.8}
\end{equation*}
$$

Substitution of (A.8) into (A.4) yields

$$
\begin{align*}
{\left[\frac{\partial}{\partial J_{B}} O\left(\left\{J_{A}\right\}\right)\right] } & =\int \prod_{\substack{A \subset \Omega \\
A \neq B}} \mathrm{~d} J_{A} P_{A}\left(J_{A}\right) \mathrm{d} J_{B}\left(\frac{\partial}{\partial J_{B 0}} P_{B}\left(J_{B}\right)\right) O\left(\left\{J_{A}\right\}\right) \\
& =\frac{\partial}{\partial J_{B 0}} \int \prod_{A \subset \Omega} \mathrm{~d} J_{A} P_{A}\left(J_{A}\right) O\left(\left\{J_{A}\right\}\right) \\
& =\frac{\partial}{\partial J_{B 0}}\left[O\left(\left\{J_{A}\right\}\right)\right] . \tag{A.9}
\end{align*}
$$
