**Abstract**

We investigate the  $g_2$ -invariant bulk (1+1D, factorized)  $S$ -matrix constructed by Ogievetsky, using the bootstrap on the three-point coupling of the vector multiplet to constrain its CDD ambiguity. We then construct the corresponding boundary  $S$ -matrix, demonstrating it to be consistent with  $Y(g_2, a_1 \times a_1)$  symmetry.

PACS number: 11.55.Bq

**1. Introduction**

As a preliminary step in the investigation using tensor methods of (1+1)-dimensional factorized  $S$ -matrices with exceptional  $\mathfrak{g}$  (and Yangian  $Y(\mathfrak{g})$ ) invariance, we investigate the case  $\mathfrak{g} = g_2$ . The factorized  $S$ -matrix for the seven-dimensional representation  $\mathbf{7}$  of  $g_2$  was constructed by Ogievetsky [1], and we use this to construct the  $(g_2 \times g_2)$ -invariant  $S$ -matrix, applicable in the principal chiral model (PCM). We may choose the  $S$ -matrix to have a bootstrap pole for the self-coupling of the  $\mathbf{7}$  multiplet, and the bootstrap applied to this process constrains the CDD factor.

We then investigate the corresponding solutions of the boundary Yang–Baxter equations and the boundary  $S$ -matrices for the  $g_2$  PCM—that is, the extension to  $g_2$  of the calculations carried out for classical  $\mathfrak{g}$  in [2]. The spectral decomposition is precisely that expected from the  $Y(g_2, a_1 \times a_1)$  symmetry [3].

The method used is the diagrammatic technique of Cvitanovic [4]. We denote the cubic antisymmetric invariant of  $g_2$  as  $\mathcal{Y}$ , then construct the  $\mathbf{7}$  of  $g_2$  by taking the defining representation of  $SO(7)$  and restricting to those  $\rho \in SO(7)$  such that  $\mathcal{Y}\rho = \mathcal{Y}$ . Here  $\mathcal{Y}$  satisfies the identities

$$\text{---}\diamond\text{---} = -6\text{---} \quad \mathcal{Y} + \mathcal{Y} = 2\mathcal{X} - \text{---} - \text{---} \quad (1.1)$$

and it is (sometimes repeated) application of these which is needed to carry out the calculations. If we take the tensor product

$$7 \otimes 7 = 27 \oplus 14 \oplus 7 \oplus 1$$

then the projectors onto the irreducible  $g_2$ -representations are

$$\begin{aligned} P_{27} &= \frac{1}{2} \left( \begin{array}{c} \text{---} \\ \text{---} \end{array} + \begin{array}{c} \times \\ \times \end{array} \right) - \frac{1}{7} \left( \begin{array}{c} \text{---} \\ \text{---} \end{array} \right) \\ P_{14} &= \frac{1}{2} \left( \begin{array}{c} \text{---} \\ \text{---} \end{array} - \begin{array}{c} \times \\ \times \end{array} \right) + \frac{1}{6} \begin{array}{c} \text{---} \\ \text{---} \end{array} \\ P_7 &= -\frac{1}{6} \begin{array}{c} \text{---} \\ \text{---} \end{array} \\ P_1 &= \frac{1}{7} \left( \begin{array}{c} \text{---} \\ \text{---} \end{array} \right) \end{aligned}$$

## 2. The bulk $S$ -matrix

The following  $g_2$ -invariant  $S$ -matrix satisfies the Yang–Baxter equation [1, 5]:

$$S_{(1,1)}(\theta) = S(\theta) = \sigma(\theta) (P_{27} + [2]P_{14} + [8]P_7 + [2][12]P_1)$$

where  $\sigma(\theta)$  is a scalar prefactor and

$$[y] = \frac{\frac{y i \pi}{12} + \theta}{\frac{y i \pi}{12} - \theta}.$$

Imposing  $R$ -matrix unitarity on the  $S$ -matrix gives  $\sigma(\theta)\sigma(-\theta) = 1$ , and imposing Hermitian analyticity gives  $\sigma(\theta) = \sigma(-\theta^*)^*$ . We rewrite the  $S$ -matrix as

$$S(\theta) = \omega(\theta) \left( \begin{array}{c} \text{---} \\ \text{---} \end{array} - \frac{6\theta}{i\pi} \begin{array}{c} \times \\ \times \end{array} + \frac{2\theta}{(i\pi - \theta)} \begin{array}{c} \text{---} \\ \text{---} \end{array} \right) \left( + \frac{\theta}{(\frac{2i\pi}{3} - \theta)} \begin{array}{c} \text{---} \\ \text{---} \end{array} \right) \quad (2.1)$$

where  $\sigma(\theta) = (1 - \frac{6\theta}{i\pi})\omega(\theta)$ , and impose crossing symmetry

$$\begin{aligned} \omega(\theta) \left( \begin{array}{c} \text{---} \\ \text{---} \end{array} - \frac{6\theta}{i\pi} \begin{array}{c} \times \\ \times \end{array} + \frac{2\theta}{(i\pi - \theta)} \begin{array}{c} \text{---} \\ \text{---} \end{array} \right) \left( + \frac{\theta}{(\frac{2i\pi}{3} - \theta)} \begin{array}{c} \text{---} \\ \text{---} \end{array} \right) \\ = \omega(i\pi - \theta) \left( \begin{array}{c} \text{---} \\ \text{---} \end{array} \right) \left( - \frac{6(i\pi - \theta)}{i\pi} \begin{array}{c} \times \\ \times \end{array} + \frac{2(i\pi - \theta)}{\theta} \begin{array}{c} \text{---} \\ \text{---} \end{array} + \frac{(i\pi - \theta)}{(\theta - \frac{i\pi}{3})} \begin{array}{c} \text{---} \\ \text{---} \end{array} \right). \end{aligned}$$

Using  $\begin{array}{c} \text{---} \\ \text{---} \end{array} = -\begin{array}{c} \text{---} \\ \text{---} \end{array} + 2\begin{array}{c} \times \\ \times \end{array} - \begin{array}{c} \text{---} \\ \text{---} \end{array}$  (we find that this is satisfied if

$$\omega(\theta) = \omega(i\pi - \theta) \frac{(i\pi - \theta)(\frac{2i\pi}{3} - \theta)}{\theta(\frac{i\pi}{3} - \theta)} \Leftrightarrow \sigma(\theta) = \sigma(i\pi - \theta) \frac{(i\pi - \theta)(\frac{2i\pi}{3} - \theta)(\frac{i\pi}{6} - \theta)}{\theta(\frac{i\pi}{3} - \theta)(\theta - \frac{5i\pi}{6})}.$$

To solve for  $\sigma(\theta)$  we first introduce

$$\mu_a(\theta) = \frac{\Gamma(\frac{\theta}{2i\pi} + \frac{a}{12}) \Gamma(\frac{-\theta}{2i\pi} + \frac{a}{12} + \frac{1}{2})}{\Gamma(\frac{-\theta}{2i\pi} + \frac{a}{12}) \Gamma(\frac{\theta}{2i\pi} + \frac{a}{12} + \frac{1}{2})}$$

which satisfies  $\mu_a(\theta)\mu_a(-\theta) = 1$  and, for real  $a$ ,  $\mu_a(\theta) = \mu_a(-\theta^*)^*$ . Further

$$\frac{\mu_a(\theta)}{\mu_a(i\pi - \theta)} = \frac{(\frac{ai\pi}{6} - \theta)}{(\theta - i\pi + \frac{ai\pi}{6})} = \frac{\mu_{6-a}(i\pi - \theta)}{\mu_{6-a}(\theta)}.$$

We seek a minimal  $S$ -matrix, with no poles on the physical strip. The factor  $\mu_a(\theta)$  has simple poles at  $\theta = -2i\pi n - \frac{ai\pi}{6}$ ,  $\theta = 2i\pi n + i\pi + \frac{ai\pi}{6}$  and simple zeroes at  $\theta = 2i\pi n + \frac{ai\pi}{6}$ ,  $\theta = -2i\pi n - i\pi - \frac{ai\pi}{6}$  for  $n = 0, 1, 2, \dots$ . Thus, to cancel the poles in (2.1) we are led to

$$\sigma(\theta) = \mu_0(-\theta)\mu_1(\theta)\mu_3(\theta)\mu_4(\theta)$$

so that

$$\sigma(\theta) = \frac{\Gamma(\frac{\theta}{2i\pi} + \frac{1}{2})\Gamma(\frac{-\theta}{2i\pi})\Gamma(\frac{-\theta}{2i\pi} + \frac{7}{12})\Gamma(\frac{\theta}{2i\pi} + \frac{1}{12})\Gamma(\frac{-\theta}{2i\pi} + \frac{3}{4})\Gamma(\frac{\theta}{2i\pi} + \frac{1}{4})\Gamma(\frac{-\theta}{2i\pi} + \frac{5}{6})\Gamma(\frac{\theta}{2i\pi} + \frac{1}{3})}{\Gamma(\frac{-\theta}{2i\pi} + \frac{1}{2})\Gamma(\frac{\theta}{2i\pi})\Gamma(\frac{\theta}{2i\pi} + \frac{7}{12})\Gamma(\frac{-\theta}{2i\pi} + \frac{1}{12})\Gamma(\frac{-\theta}{2i\pi} + \frac{3}{4})\Gamma(\frac{\theta}{2i\pi} + \frac{1}{4})\Gamma(\frac{-\theta}{2i\pi} + \frac{5}{6})\Gamma(\frac{-\theta}{2i\pi} + \frac{1}{3})}$$

(in fact we may choose plus or minus this—our choice of the positive sign will not affect the  $S$ -matrix). Thus we have established a minimal  $S$ -matrix which is  $g_2$  invariant.

The  $g_2$  PCM  $S$ -matrix acts on multiplets which are representations of  $(g_2 \times g_2)$ , and is constructed from two minimal  $S$ -matrices together with a CDD factor  $X(\theta)$ :

$$S_{(1,1)}^{PCM}(\theta) = X_{(1,1)}(\theta)(S(\theta)_L \otimes S(\theta)_R).$$

In order that  $S_{(1,1)}^{PCM}(\theta)$  satisfy  $R$ -matrix unitarity and crossing-symmetry we require

$$X_{(1,1)}(\theta)X_{(1,1)}(-\theta) = 1 \quad \text{and} \quad \frac{X_{(1,1)}(\theta)}{X_{(1,1)}(i\pi - \theta)} = 1.$$

To construct  $X$  we use

$$(y) = (y)_\theta = \frac{\sinh(\frac{\theta}{2} + \frac{y i \pi}{24})}{\sinh(\frac{\theta}{2} - \frac{y i \pi}{24})}$$

this satisfies

$$(y)_\theta (y)_{-\theta} = 1 \quad \frac{(y)_\theta}{(y)_{i\pi - \theta}} = (2y)_{2\theta} \quad \text{and} \quad (y) = (y + 24).$$

The natural choice might be  $X = -(2)(4)(8)(10)$ , where we have allowed two **7**s to fuse (via simple poles with positive residues) to form either a **7** (at  $\theta = 2i\pi/3$ ) or a **14**  $\oplus$  **1** (at  $\theta = i\pi/6$ , yielding a multiplet of mass  $2 \cos(\pi/12) = \frac{1}{2}(\sqrt{6} + \sqrt{2})$  times the mass of the **7**). We must then check that the bootstrap equations are satisfied for the scattering of a **7** off a fused **7**  $\subset$  **7**  $\otimes$  **7** (an intricate calculation requiring much repeated application of (1.1)). The minimal  $S$ -matrix is consistent with this, but the CDD factor requires an extra factor  $(6)^2$ , and we must have

$$X_{(1,1)}(\theta) = -(2)(4)(6)^2(8)(10).$$

The apparent double pole at  $i\pi/2$  thus introduced is spurious: it is cancelled by a simple zero in each minimal  $S$ .

### 3. The boundary $S$ -matrix

We now consider the half-line case. Following [2], we try a minimal boundary  $S$ -matrix of the form

$$K(\theta) = \frac{\tau(\theta)}{(1 - c\theta)} (\text{---} + c\theta \text{---} \text{---} \text{---}).$$

The conditions of boundary  $R$ -matrix unitarity and Hermitian analyticity impose the constraints

$$\begin{aligned} (\text{---} \text{---})^\dagger &= \text{---} \text{---} & \text{---} \text{---} \text{---} &= \text{---} & c &\in i\mathbb{R} & \tau(\theta) &= \tau(-\theta^*)^* & \text{and} \\ \tau(\theta)\tau(-\theta) &= 1. \end{aligned}$$

We must also impose crossing-unitarity

$$\begin{aligned} \frac{\tau(\frac{i\pi}{2} - \theta)}{(1 - c(\frac{i\pi}{2} - \theta))} \left( \text{---} + c \left( \frac{i\pi}{2} - \theta \right) \text{---} \right) &= \frac{\omega(i\pi - 2\theta)\tau(\frac{i\pi}{2} + \theta)}{(1 - c(\frac{i\pi}{2} + \theta))} \left( \text{---} \right) \left( -\frac{6(i\pi - 2\theta)}{i\pi} \text{---} \right) \\ &+ \frac{(i\pi - 2\theta)}{\theta} \text{---} + \frac{(i\pi - 2\theta)}{(2\theta - \frac{i\pi}{3})} \text{---} \left( \text{---} + c \left( \frac{i\pi}{2} + \theta \right) \text{---} \right). \end{aligned}$$

After applying (1.1) we find that this implies

$$\begin{aligned} \frac{\tau(\frac{i\pi}{2} - \theta)}{\tau(\frac{i\pi}{2} + \theta)} &= \frac{\omega(i\pi - 2\theta)(1 - c(\frac{i\pi}{2} - \theta))(\theta - \frac{i\pi}{3})}{(1 - c(\frac{i\pi}{2} + \theta))(2\theta - \frac{i\pi}{3})} \left( 14 + 2i\pi c \textcircled{\circ} + \frac{i\pi}{\theta} + 4 \left( c \textcircled{\circ} + \frac{6}{i\pi} \right) \theta \right) \\ &\times \frac{\tau(\frac{i\pi}{2} - \theta)}{\tau(\frac{i\pi}{2} + \theta)} = \frac{\omega(i\pi - 2\theta)(1 - c(\frac{i\pi}{2} - \theta))(\theta - \frac{i\pi}{3})(i\pi + 2\theta)}{(1 - c(\frac{i\pi}{2} + \theta))(2\theta - \frac{i\pi}{3})} \\ &\times \left( \frac{-\alpha}{(\theta - \frac{i\pi}{3})} + \frac{1}{\theta} \mp \frac{12}{i\pi} \right) \end{aligned}$$

together with (for non-trivial  $\textcircled{\circ}$ )  $\textcircled{\circ} \times \textcircled{\circ} = \pm \textcircled{\circ}$  and  $\textcircled{\circ} \textcircled{\circ} = \alpha \textcircled{\circ}$  for some constant  $\alpha$ . Comparing the two expressions we find  $\alpha = 0$  and

$$c \textcircled{\circ} = -\frac{6(1 \pm 1)}{i\pi}.$$

However,  $\textcircled{\circ} = 0$  together with  $\textcircled{\circ} \textcircled{\circ} = \textcircled{\circ}$  has no solutions in odd dimensions (the eigenvalues of such a matrix are  $\pm 1$ , an odd number of which cannot sum to zero). We thus have  $(\textcircled{\circ})^t = \textcircled{\circ}$  and

$$\frac{\tau(\frac{i\pi}{2} - \theta)}{\tau(\frac{i\pi}{2} + \theta)} = \frac{\omega(i\pi - 2\theta)(1 - c(\frac{i\pi}{2} - \theta))(\theta - \frac{i\pi}{3})(i\pi + 2\theta)}{(1 - c(\frac{i\pi}{2} + \theta))(2\theta - \frac{i\pi}{3})} \left( \frac{1}{\theta} - \frac{12}{i\pi} \right)$$

or

$$\frac{\tau(\frac{i\pi}{2} - \theta)}{\tau(\frac{i\pi}{2} + \theta)} = [6] \left[ \frac{12}{ci\pi} - 6 \right] \sigma(2\theta) \quad (\textcircled{\circ})^t = \textcircled{\circ} \quad \text{and} \quad c \textcircled{\circ} = -\frac{12}{i\pi}.$$

Last we have to impose the boundary Yang–Baxter equation (bYBe). After some algebra we find that this is satisfied if

$$\textcircled{\circ} + \textcircled{\circ} = \frac{ci\pi}{12} \textcircled{\circ}.$$

Now using (1.1) we find

$$\textcircled{\circ} = \textcircled{\circ} + \frac{12}{ci\pi} \textcircled{\circ}.$$

Thus, putting these two results together

$$\textcircled{\circ} = \frac{ci\pi}{12} \textcircled{\circ} \Leftrightarrow \textcircled{\circ} = \frac{ci\pi}{12} \textcircled{\circ}.$$

Consequently we must have  $c = \pm \frac{12}{i\pi}$ , with  $\textcircled{\circ} = \pm \textcircled{\circ}$  and  $\textcircled{\circ} = \mp 1$ .

In summary, we have shown that the conditions of  $R$ -matrix unitarity, Hermitian analyticity, crossing unitarity and the bYBe are satisfied by a minimal boundary ‘ $K$ ’-matrix

$$\frac{\tau(\theta)}{(1 \mp \frac{12\theta}{i\pi})} \left( \textcircled{\circ} \pm \frac{12\theta}{i\pi} \textcircled{\circ} \right) = \tau(\theta)(P_-[\pm 1]P_+) \quad \left( P_{\pm} = \frac{1}{2}(\textcircled{\circ} \pm \textcircled{\circ}) \right)$$

where

$$\begin{aligned} (\textcircled{\circ})^{\dagger} &= \textcircled{\circ} & (\textcircled{\circ})^t &= \textcircled{\circ} & \textcircled{\circ} \textcircled{\circ} &= \textcircled{\circ} & \textcircled{\circ} \textcircled{\circ} &= \pm \textcircled{\circ} & \textcircled{\circ} &= \mp 1 \\ \tau(\theta)\tau(-\theta) &= 1 & \tau(\theta) &= \tau(-\theta)^* & \frac{\tau(\frac{i\pi}{2} - \theta)}{\tau(\frac{i\pi}{2} + \theta)} &= [6][\pm 1 - 6]\sigma(2\theta). \end{aligned}$$

In fact, since  $[1]_{\frac{i\pi}{2}-\theta}/[1]_{\frac{i\pi}{2}+\theta} = [-7]/[-5]$ , the choice of sign is redundant—both choices give the same minimal  $K$ -matrix. We can write it as

$$\frac{\tau(\theta)}{\left(1 - \frac{12\theta}{i\pi}\right)} \left(I + \frac{12\theta}{i\pi} E\right) = \tau(\theta)(P_-[1]P_+) \quad \left(P_{\pm} = \frac{1}{2}(I \pm E)\right)$$

where  $E = QXQ^{-1}$ ,  $Q \in G_2$ ,  $X = \text{diag}(1, 1, 1, -1, -1, -1, -1)$ . This is clearly a subspace of the symmetric space  $SO(7)/S(O(3) \times O(4))$ ; in fact we have

$$E \in \frac{G_2}{SU(2) \times SU(2)}$$

the space of quaternionic subalgebras of the octonions, as may be seen by considering the action of  $G_2$  on a basic triple of octonions [6].

The following constraints are imposed on  $\tau(\theta)$ :

$$\tau(\theta)\tau(-\theta) = 1 \quad \tau(\theta) = \tau(-\theta^*)^* \quad \frac{\tau\left(\frac{i\pi}{2} - \theta\right)}{\tau\left(\frac{i\pi}{2} + \theta\right)} = [6] [-5] \sigma(2\theta).$$

To solve these we note that

$$\frac{\mu_a\left(\frac{i\pi}{2} - \theta\right)}{\mu_a\left(\frac{i\pi}{2} + \theta\right)} = -[2a - 6]$$

and we define

$$\eta_a(\theta) = \frac{\Gamma\left(\frac{-\theta}{2i\pi} + \frac{a}{12}\right) \Gamma\left(\frac{\theta}{2i\pi} + \frac{a}{12} + \frac{1}{4}\right)}{\Gamma\left(\frac{\theta}{2i\pi} + \frac{a}{12}\right) \Gamma\left(\frac{-\theta}{2i\pi} + \frac{a}{12} + \frac{1}{4}\right)} \quad \text{so that} \quad \frac{\eta_a\left(\frac{i\pi}{2} - \theta\right)}{\eta_a\left(\frac{i\pi}{2} + \theta\right)} = \mu_{2a-6}(2\theta).$$

This leads us to

$$\tau(\theta) = \mu_{1/2}(\theta)\mu_6(\theta)\eta_{7/2}(\theta)\eta_{9/2}(\theta)\eta_5(\theta)\eta_6(\theta).$$

The simple poles of  $\eta_a(\theta)$  are at  $\theta = 2i\pi n + \frac{ai\pi}{6}$  and  $\theta = -2i\pi n - \frac{i\pi}{2} - \frac{ai\pi}{6}$ , while the simple zeroes are at  $\theta = -2i\pi n - \frac{ai\pi}{6}$  and  $\theta = 2i\pi n + \frac{i\pi}{2} + \frac{ai\pi}{6}$ , and so the  $K$ -matrix is minimal.

The final piece we require for the complete PCM  $K$ -matrix is the factor  $Y_1(\theta)$ , which must satisfy

$$\frac{Y_1\left(\frac{i\pi}{2} - \theta\right)}{Y_1\left(\frac{i\pi}{2} + \theta\right)} = X_{(1,1)}(i\pi - 2\theta) = X_{(1,1)}(2\theta).$$

We make use of the fact that

$$\frac{(y)_{\frac{i\pi}{2}-\theta}}{(y)_{\frac{i\pi}{2}+\theta}} = (2y)_{i\pi-2\theta} = (2y+24)_{i\pi-2\theta}.$$

Thus the most natural choice is

$$Y_1(\theta) = (1)(2)(-9)^2(-8)(-7)(-6).$$

This has a physical strip simple pole at  $\theta = \frac{i\pi}{12}$  at which the minimal  $K$ -matrix projects onto the subspace associated with  $P_+$  (the smaller one, and the  $(\mathbf{3}, \mathbf{1})$  of  $(a_1 \times a_1)$  as found in [3]). The simple pole at  $\theta = \frac{i\pi}{6}$  corresponds to an on-shell diagram which is possible precisely when the bulk 3-point coupling of 7s exists.

We should also check the simpler trial solution of [2] for a minimal  $K$ -matrix, namely

$$K(\theta) = \rho(\theta) \text{---} \ominus \text{---}.$$

Imposing crossing-unitarity gives

$$\frac{\rho(\frac{i\pi}{2} - \theta)}{\rho(\frac{i\pi}{2} + \theta)} \left\langle \right\rangle = \omega(i\pi - 2\theta) \left( \frac{4(\theta - \frac{i\pi}{3})}{(2\theta - \frac{i\pi}{3})} \right) \left( + \frac{4(i\pi - 2\theta)(i\pi - 3\theta)}{i\pi(2\theta - \frac{i\pi}{3})} \right. \\ \left. + \frac{(i\pi - 2\theta)(\theta - \frac{i\pi}{3})}{\theta(2\theta - \frac{i\pi}{3})} \left\langle \right\rangle + \frac{(i\pi - 2\theta)}{(2\theta - \frac{i\pi}{3})} \left\langle \right\rangle \right)$$

which implies

$$\frac{\rho(\frac{i\pi}{2} - \theta)}{\rho(\frac{i\pi}{2} + \theta)} \left\langle \right\rangle = \omega(i\pi - 2\theta) \left( \frac{4(\theta - \frac{i\pi}{3})}{(2\theta - \frac{i\pi}{3})} \right) \left\langle \right\rangle + \frac{4(i\pi - 2\theta)(i\pi - 3\theta)}{i\pi(2\theta - \frac{i\pi}{3})} \left\langle \right\rangle \\ + \frac{(i\pi - 2\theta)(\theta - \frac{i\pi}{3})}{\theta(2\theta - \frac{i\pi}{3})} \left\langle \right\rangle + \frac{(i\pi - 2\theta)}{(2\theta - \frac{i\pi}{3})} \left\langle \right\rangle.$$

For non-trivial  $\left\langle \right\rangle$  we must have  $\left\langle \right\rangle = 0$ ,  $(\left\langle \right\rangle)' = \pm \left\langle \right\rangle$  and  $\left\langle \right\rangle = \alpha \left\langle \right\rangle$ . But, as pointed out earlier, the constraint  $\left\langle \right\rangle = 0$  is inconsistent with  $\left\langle \right\rangle = \left\langle \right\rangle$ . Thus there are no non-trivial solutions of this form.

### Acknowledgments

NJM would like to thank Tony Sudbery for a helpful discussion of the octonions, and BJS would like to thank the UK EPSRC for a PhD studentship.
