## Abstract

We exclude the center of mass of the *N*-particle rational Calogero model and consider the angular part of the resulting Hamiltonian. We show that it describes the motion of the particle on an (N - 2)-dimensional sphere interacting with N(N - 1)/2 force centers with Higgs oscillator potential. In the case of a four-particle system, these force centers define the vertexes of an Archimedean solid called a cuboctahedron.

## 1. Introduction

The Calogero model [1-3] and its various extensions and generalizations play a distinguished role among other multi-particle integrable systems. They have attracted much attention due to their rich internal structure and numerous applications in many areas of physics (see, e.g., the recent review [4] and references therein).

In the continuum or thermodynamic limit, i.e. for large particle numbers, the Calogero model gives rise to a Yang–Mills theory [5] on a cylinder, while its superconformal extension describes a black hole in the near-horizon limit [6]. In this limit, the system has soliton solutions corresponding to the fundamental excitations [7].

The quantum Calogero model describes free particles with fractional statistics whose type is determined by the interaction strength [8]. Moreover, the variational ground state of the fractional quantum Hall effect (known as the Laughlin state [9]) can be considered as some deformation of the ground state of the Calogero model [10]. The trigonometric analog of the model [11] is related to integrable spin-1/2 chains with long-range interactions, which possess

1751-8113/09/205206+11\$30.00 © 2009 IOP Publishing Ltd Printed in the UK

a resonating-valence-bond ground state [12]. Recently, the relation with the Benjamin–Ono equation arising in the hydrodynamics of stratified fluids has been established [13].

The Calogero model and its modifications appear also in matrix models [14],  $W_{\infty}$ -algebras [15], Yangian quantum groups [16], random matrices [17] and many other areas of physics and mathematics.

In this paper, we will study the classical rational Calogero system without confining potential. It describes one-dimensional particles with inverse-square interaction [1-3]:

$$\mathcal{H} = \frac{1}{2} \sum_{i=1}^{N} p_i^2 + \sum_{i < j} \frac{g}{(x_i - x_j)^2}, \qquad \{p_i, x_j\} = \delta_{ij}.$$
 (1)

One of the important features of the system is its manifest conformal invariance, which was essential for the invention of the model, as well as for its further studies.

In the pioneering paper [1], the three-particle model was considered first. After excluding the center of mass (with *a priori* conserving momentum) and taking into account the conformal invariance, the model was reduced to a one-dimensional exactly solvable system on a circle considered by Jacobi in the middle of the 19th century [18]:

$$\mathcal{I} = \frac{p_{\varphi}^2}{2} + \frac{9g}{2\cos^2 3\varphi}.$$
 (2)

For more particles, the analysis of the Calogero model becomes more complicated. In particular, the construction of the complete set of the constants of motion assumes the use of the powerful method of the Lax pair [3]. This approach allowed us to relate the Calogero system to  $A_{N-1}$  Lie algebras, as well as to construct its integrable modifications related to other Lie algebras [19]. The Calogero systems can be obtained from the free-particle system by an appropriate reduction procedure known as the projection method [20]. Recently, it has been generalized to the Calogero model extensions corresponding to the root systems [21].

However, the analog of the system (2) has not been properly studied for the case of more than three particles. Such a study would be an interesting problem from a few viewpoints.

Already in the pioneering papers [1, 2], it was observed that the spectrum of the Calogero model with additional oscillator potential is similar to the spectrum of a free *N*-dimensional oscillator. It was claimed there that a similarity transformation to the free-oscillator system may exist, at least, in the part of the Hilbert space. However, this transformation was written explicitly only three decades later [22]. In [23], it was related to the conformal group SU(1, 1). This similarity transformation has a very transparent geometric explanation for the two-particle Calogero model (the 'conformal mechanics'): it corresponds to the inversion in the Klein model of the Lobachevsky space, which describes the phase space of the system. A natural way to extend this picture to the multi-particle Calogero system is to identify the coordinates of its 'radial' part with the coordinates of the Klein model. In other words, one must extract and investigate the angular part of the system.

Another motivation is connected with the superconformal extensions of the Calogero model. In [23], the authors suggested to use the aforementioned similarity transformation for the construction of the  $\mathcal{N} = 4$  superconformal Calogero system [25]. However, the suggested algebraic scheme is quite nontrivial, and for the cases of four and more particles it assumes the solving of WDVV and other partial differential equations. On the other hand, in [27] the superconformal extension of the three-particle Calogero model was constructed in a transparent way within the superfield approach by extracting the model (2) from the initial system. This approach seems to be applicable to the any-particle Calogero system, under the assumption that its angular part admits  $\mathcal{N} = 4$  supersymmetric extension.

The other stimulus for the study of the angular part of the Calogero model is the translation of the discrete symmetries of the one-dimensional multi-particle system to the higher-dimensional one-particle one. This would provide us with *a priori* integrable higher-dimensional one-particle system with some discrete symmetry.

The purpose of the current paper is the investigation of the angular part of the *N*-particle Calogero model with the excluded center of mass. Like in the three-particle case, it is a constant of motion. Hence, its Poisson brackets with the Liouville constants of motions can generate the additional constants of motions. This can give a simple explanation of the superintegrability of the Calogero model observed many years ago by Wojciechowski [28]. We show that the angular part itself describes a particle on the (N - 2)-dimensional sphere, which interacts with the N(N - 1)/2 force centers by the Higgs oscillator low. Briefly speaking, we have a N(N - 1)/2-center (N - 2)-dimensional Higgs oscillator. For the N = 4 case corresponding to particle motion on a two-dimensional sphere, the force centers are located at the vertexes of the Archimedean solid cuboctahedron. This observation opens a few horizons for further study of the Calogero model. In particular, the investigation of the angular part of the spin-Calogero model and/or its supersymetric extensions becomes especially important due to the possibility of applications in solid state physics.

The paper is organized as follows.

In section 2, we exclude the center of mass from the *N*-particle Calogero model and obtain an (N - 1)-dimensional system characterized by N(N - 1)/2 unit vectors. These vectors correspond to the positive roots of the Lie algebra  $A_{N-1}$ . Then we show that the angular part of the reduced system describes a particle on the (N - 2)-dimensional sphere interacting with the vertexes of the aforementioned vectors by the Higgs oscillator low.

In section 3, we illustrate the general analysis of section 2 for the simplest nontrivial case of the three-particle Calogero model. The corresponding angular part is given by (2). We show that its Poisson bracket with the third-order Liouville constant of motion coincides with the additional constant of motion. Then we derive an explicit functional dependence between four constants of motion (including the Hamiltonian).

In section 4, we consider the four-particle system. We show that its angular part describes a multicenter Higgs oscillator on a two-dimensional sphere with force centers located at the vertexes of the cuboctahedron.

In the last section, we summarize the results and discuss the possible extension to the supersymmetric Calogero systems.

#### 2. The center-of-mass system

In order to decouple the center of mass, we introduce a new coordinate system for the *N*-particle Calogero model:

$$y_{0} = \frac{1}{\sqrt{N}} \sum_{i=1}^{N} x_{i}, \qquad y_{k} = \frac{1}{\sqrt{N-k+1}} \left( \sqrt{N-k} x_{k} - \frac{1}{\sqrt{N-k}} \sum_{i=k+1}^{N} x_{i} \right),$$

$$1 \le k \le N-1.$$
(3)

Here  $y_0$  describes the center-of-mass movement, while the remaining  $y_k$  describe the motion in the center-of-mass system. The transformation (3) is chosen to be orthogonal:

$$\sum_{k=1}^{N} (\mathrm{d}x_k)^2 = (\mathrm{d}y_0)^2 + \sum_{k=1}^{N-1} (\mathrm{d}y_k)^2.$$

3

Hence, the inverse transformation  $x_k = \sum_{n=1}^{N} A_{kn} y_n$  coincides with its transpose:

$$A_{km} = \begin{cases} 1/\sqrt{N} & \text{for } m = 0\\ -1/\sqrt{(N-m+1)(N-m)} & \text{for } k > m \ge 1\\ \sqrt{N-k}/\sqrt{N-k+1} & \text{for } m = k\\ 0 & \text{for other } m. \end{cases}$$

Using these formulae, we rewrite the Hamiltonian of the Calogero model in terms of the center-of-mass variables:

$$\mathcal{H} = \frac{1}{2} \sum_{i=1}^{N} p_i^2 + \sum_{i < j} \frac{g}{(x_i - x_j)^2} = \frac{p_0^2}{2} + \tilde{\mathcal{H}}.$$

Here  $p_0 = \sum_{i=1}^{N} p_i$  is the conserved total momentum of the *N*-particle Calogero system. The last term is given by the expression

$$\tilde{\mathcal{H}} = \frac{1}{2} \sum_{i=1}^{N-1} p_i^2 + \sum_{a=1}^{N(N-1)/2} \frac{g}{2\left(\sum_{k=1}^{N-1} b_k^a y_k\right)^2}, \qquad \{p_i, y_j\} = \delta_{ij}, \tag{4}$$

where  $a \equiv (i, j)$  enumerates the pairs of interacting particles,  $p_i$  (we keep the old notation for them) are the new momenta conjugated to  $y_i$ , and

$$b_k^a = b_k^{ij} = \frac{A_{ik} - A_{jk}}{\sqrt{2}}.$$
(5)

It is clear that the Hamiltonian with the excluded center of mass  $\tilde{\mathcal{H}}$  is a constant of motion of the original system (1). From the orthogonality of the matrix  $A_{ik}$  we have

$$\sum_{k} (b_{k}^{ij})^{2} = 1,$$

$$\cos \alpha_{ij,i'j'} = \sum_{k} b_{k}^{ij} b_{k}^{i'j'} = \frac{1}{2} \sum_{k} (A_{ik} - A_{jk}) (A_{i'k} - A_{j'k})$$

$$= \frac{1}{2} (\delta_{ii'} + \delta_{jj'} - \delta_{ij'} - \delta_{i'j}).$$
(6)

So, the coordinates  $\mathbf{b}^a = (b_1^a, \dots, b_{N-1}^a)$  define unit vectors in (N-1)-dimensional space, while  $\alpha_{ij,i'j'}$  are the angles between them. In fact,  $\mathbf{b}^a$  correspond to the positive roots of the Lie algebra  $A_{N-1}$  (rescaled by the factor  $1/\sqrt{2}$ ). Indeed, the potential of the original model (1) can be presented as the inverse-square sum over all positive roots  $\Delta_+$  of  $A_{N-1}$  multiplied by the particle coordinates:  $\sum_{\alpha \in \Delta_+} g/(\alpha \cdot \mathbf{x})^2$  [20]. The orthogonal transformation (3) acts on those roots by mapping them onto  $\mathbf{b}^a$ . Therefore, the last vectors define the same root system.

The reduced system (4), (5) can be interpreted as a one-particle system in (N - 1)-dimensional space. Let us extract the radius *r* of the obtained system. This can be done, for instance, in hyperspherical coordinates, where the Hamiltonian (4) takes the following form:

$$\tilde{\mathcal{H}} = \frac{p_r^2}{2} + \frac{\mathcal{I}(p_{\varphi_a}, \varphi_{\alpha})}{r^2}, \qquad \mathcal{I}(p_{\varphi_{\alpha}}, \varphi_{\alpha}) = \frac{K_{\rm sph}(p_{\varphi_{\alpha}}, \varphi_{\alpha})}{2} + \sum_a \frac{g}{2\cos^2\theta_a}, \qquad (7)$$

$$\{p_{\varphi_{\alpha}}, \varphi_{\alpha}\} = \delta_{\alpha\beta},$$

where  $\alpha, \beta = 2, ..., N - 1$ . Here  $K_{sph}$  is the standard kinetic term of the particle on the hypersphere  $S^{N-2}$  with unit radius,  $\theta_a$  is the angle between  $\mathbf{b}_a$  and the unit vector  $\mathbf{n} = \mathbf{r}/r$  directed from the hypersphere center to the particle.

Since  $\mathcal{I}$  is independent from the radial coordinates  $p_r$  and r, it commutes with the Hamiltonian  $\tilde{\mathcal{H}}$ . So, it is a constant of motion of the Calogero model. Note that this integral

is quadratic on the momenta (while in the standard Lax pair approach, the only constant of motion which is quadratic on momenta is the Hamiltonian). It is easy to verify that any other integral being in involution with  $\mathcal{I}$  must depend on the radial coordinates through the Hamiltonian  $\tilde{\mathcal{H}}$ . Therefore, it is not in involution, at least, with the integrals having an odd order on  $p_r$  and is functionally independent from the *N* commuting integrals constructed using the Lax pair. The matter is that the Calogero model is not only an integrable in the Liouville sense (which means the existence of *N* integrals being in involution) but also is maximally superintegrable with 2N - 1 functionally independent integrals [28] (see also [29]). Clearly,  $\mathcal{I}$  is a function of this complete set of the constants of motion. Moreover, its Poisson bracket action on the Liouville constants of motions generates the additional constants of motion, which are responsible for the superintegrability.

It can be considered as the Hamiltonian of a particle moving on the (N - 2)-dimensional sphere with N(N - 1)/2 force centers defined by the vectors  $\mathbf{b}^a$ . Since this system is invariant under reflections  $\mathbf{b}^a \rightarrow -\mathbf{b}^a$  for any *a*, sometimes it is reasonable to consider the N(N - 1) properly located force centers. In order to clarify the physical meaning of the obtained system, let us rewrite its potential as follows:

$$V_{\rm sph} = \sum_{a} \frac{g}{2\cos^2\theta_a} = \frac{N(N-1)g}{4} + \frac{g}{2} \sum_{a} \tan^2\theta_a.$$

Recall now that

$$V_{\rm Higgs} = \frac{\omega^2 r_0^2 \tan^2 \theta}{2}$$

is the well-known potential of the Higgs oscillator. It generalizes the ordinary oscillator potential for the sphere with the radius  $r_0$  and inherits all its hidden symmetries [32].

Hence, we obtained the integrable N(N-1)/2-center N-dimensional Higgs oscillator of the frequency  $\omega = \sqrt{g}$ .

The location of the force centers is quite rigid and deserves to be considered in more detail. Note that the Higgs oscillator was invented about 30 years ago and has been studied in hundreds of papers so far (see, e.g., [33] and references therein). Nevertheless, its anisotropic version was found quite recently [34], whereas the two-center version is not known yet, up to our knowledge.

#### 3. The three-particle case: circle

The simplest system is the angular part of the three-particle model considered in the pioneering paper by Calogero [1]. Actually, this system was considered in the middle of the 19th century by Jacobi [18] (see also [35]). For N = 3, we get a particle on the circle  $S^1$  with three force centers defined by the unit vectors  $\mathbf{b}^{12}$ ,  $\mathbf{b}^{23}$  and  $\mathbf{b}^{13}$ . The angles between them are equal to  $\pi/3$  and  $2\pi/3$  (figure 1):

$$\cos \alpha_{12,13} = \cos \alpha_{13,23} = 1/2, \qquad \cos \alpha_{12,23} = -1/2.$$

The above vectors make up the set of positive roots of  $A_2 \equiv su(3)$  Lie algebra. Completing them by the oppositely directed vectors corresponding to the negative roots, we obtain a system with six force centers. The angular part of the Hamiltonian,

$$\mathcal{I} = \frac{p_{\varphi}^2}{2} + \frac{g}{2\cos^2\varphi} + \frac{g}{2\cos^2(\varphi + \pi/3)} + \frac{g}{2\cos^2(\varphi - \pi/3)} = \frac{p_{\varphi}^2}{2} + \frac{9g}{1 + \cos 6\varphi},\tag{8}$$

coincides with (2). It is invariant under the rotation on  $\pi/3$  and the reflection  $\varphi \rightarrow -\varphi$ , which generate the symmetry group  $D_6 \equiv S_3 \otimes Z_2$  of the hexagon (figure 1). Here  $S_3$  is the

**Figure 1.** The force centers  $(\mathbf{b}^{12}, \mathbf{b}^{23}, \mathbf{b}^{13})$  and their opposites), which form the root system of su(3) and constitute an hexagon. The angle  $\varphi$  describes the position of a particle on the cycle.

symmetric group of three-particle permutations, which  $\mathcal{I}$  inherits from the original Calogero Hamiltonian (1). The  $Z_2$ -symmetry corresponds to the reflection invariance  $x_i \rightarrow -x_i$  of (1). The integrability of this system is obvious. Note that the splitting of the three-particle Calogero Hamiltonian on the angular and radial parts has been used in [31] for the detailed study of the quantization.

Let us briefly discuss the relation of the system on a circle with the superintegrability of the three-particle Calogero model. Note that its superintegrability was studied in detail (see [30] and references therein). In the center-of-mass system, three from the five functionally independent constants of motion of the original Calogero system survive. Namely, the Hamiltonian of the two-particle system,  $\tilde{\mathcal{H}} = p_r^2/2 + \mathcal{I}/r^2$ , and its constant of motion,

$$\mathcal{F} = \left(p_r^2 - \frac{6\mathcal{I}}{r^2}\right) p_r \sin 3\varphi + \left(3p_r^2 - \frac{2\mathcal{I}}{r^2}\right) \frac{p_\varphi \cos 3\varphi}{r},\tag{9}$$

are reduced from the second- and third-order (on momentum) Liouville constants of motion. Similarly, the third conserved quantity,

$$\mathcal{K} = \left(p_r^2 - \frac{6\mathcal{I}}{r^2}\right) p_r p_\varphi \cos 3\varphi - \left(3p_r^2 - \frac{2\mathcal{I}}{r^2}\right) \frac{2\mathcal{I}\sin 3\varphi}{r},\tag{10}$$

is inherited from the additional third-order constant of motion of the three-particle Calogero system. The integrals  $\tilde{\mathcal{H}}$ ,  $\mathcal{F}$  and  $\mathcal{K}$  are functionally independent. We have expressed them in terms of the angular part of the Hamiltonian (8), which also conserves. Its Poisson bracket action maps the Liouville integral to the additional one:

$$\{\mathcal{I}, \mathcal{F}\} = 3\mathcal{K}, \qquad \{\mathcal{I}, \mathcal{K}\} = -6\mathcal{I}\mathcal{F}.$$
(11)

The four quantities  $\tilde{\mathcal{H}}, \mathcal{I}, \mathcal{F}$  and  $\mathcal{K}$  form an overcompleted set of constants of motion. They are subjected to the algebraic relation

$$\mathcal{K}^2 + 2\mathcal{IF}^2 = 8\tilde{\mathcal{H}}^3(2\mathcal{I} - 9g) \qquad \text{or} \qquad \mathcal{I} = \frac{\mathcal{K}^2 + 72g\mathcal{H}^3}{16\tilde{\mathcal{H}}^3 - 2\mathcal{F}^2}.$$
 (12)

6

**Figure 2.** The vectors (13) together with their opposites form a cuboctahedron and are equivalent to the root system of su(4). The bold points on the large cycle correspond to  $\mathbf{b}^{23}$ ,  $\mathbf{b}^{34}$  and  $\mathbf{b}^{24}$  while the small cycle contains the vertexes of the remaining three vectors. The bold lines are the axes of the coordinate system (15).

Hence, one can choose  $\tilde{\mathcal{H}}, \mathcal{I}$  and  $\mathcal{F}$  as a complete set of functionally independent conserved quantities. The first two of them are quadratic on momenta, which ensures the separation of variables in the system.

It is easy to verify that the Poisson brackets (11) are in consistency with relation (12). Finally, using (12) and the first equation in (11), we obtain the Poisson bracket between two third-order integrals:

$$\{\mathcal{K}, \mathcal{F}\} = 3(8\tilde{\mathcal{H}}^3 - \mathcal{F}^2) = 3\frac{\mathcal{K}^2 + 9g\mathcal{F}^2}{2\mathcal{I} - 9g}$$

# 4. The four-particle system: sphere

In the four-particle case, everything becomes much more complicated. In the same way, we obtain a system on the sphere with *six* force centers defined by the unit vectors  $\mathbf{b}^a$  with the following Cartesian coordinates of the ambient  $\mathbb{R}^3$  space:

$$\mathbf{b}^{12} = \left(\sqrt{\frac{2}{3}}, -\frac{1}{\sqrt{3}}, 0\right), \qquad \mathbf{b}^{13} = \left(\sqrt{\frac{2}{3}}, \frac{1}{2\sqrt{3}}, -\frac{1}{2}\right), \qquad \mathbf{b}^{14} = \left(\sqrt{\frac{2}{3}}, \frac{1}{2\sqrt{3}}, \frac{1}{2}\right),$$
(13)  
$$\mathbf{b}^{23} = \left(0, \frac{\sqrt{3}}{2}, -\frac{1}{2}\right), \qquad \mathbf{b}^{24} = \left(0, \frac{\sqrt{3}}{2}, \frac{1}{2}\right), \qquad \mathbf{b}^{34} = (0, 0, 1).$$

The vertexes of  $\mathbf{b}^{ij}$  and their opposite vectors form an Archimedean solid called a *cuboctahedron* (figure 2). This polyhedron, like a cube, has the octahedral symmetry  $O_h \equiv S_4 \otimes Z_2$  of order 48. Here  $S_4$  is the symmetric group of four-particle permutations, which preserve the original Calogero Hamiltonian (1). Note that  $S_4$  is isomorphic to the Weyl group of  $A_3$  Lie algebra and preserves the orientation of the cuboctahedron. The  $Z_2$ 

symmetry corresponds to the reflection  $x_i \rightarrow -x_i$  of all four coordinates. In the Lie algebraic description, it corresponds to the reflection symmetry of the  $A_3$  Dynkin diagram.

Note that the vectors  $\mathbf{b}^{23}$ ,  $\mathbf{b}^{34}$  and  $\mathbf{b}^{24}$  belong to the 'equatorial' plane; the angles between them are equal to  $\pi/3$  and  $2\pi/3$ . Their vertexes and the vertexes of the opposite vectors form a hexagon (figure 2). This is precisely the same picture as in the three-particle Calogero model (see figure 1). The endpoints of the vectors  $\mathbf{b}^{12}$ ,  $\mathbf{b}^{13}$ ,  $\mathbf{b}^{14}$  are located on a plane parallel to the equatorial one (figure 2). The distance between the two planes is  $\sqrt{2/3}$ . They form the (regular) triangular face of the cuboctahedron, which is shifted by the angle  $\pi/6$  with respect to the triangle ( $\mathbf{b}^{23}$ ,  $\mathbf{b}^{34}$ ,  $-\mathbf{b}^{24}$ ).

Let us choose Cartesian coordinates with the first axis directed along  $\mathbf{b}^{13}$  while the second one belongs to the plane formed by  $\mathbf{b}^{12}$  and  $\mathbf{b}^{13}$ . The frame directions then are orthogonal to the triangles of the cuboctahedron (figure 2). In the respective spherical coordinates, the angular part of the Hamiltonian reads

$$\mathcal{I} = \frac{p_{\theta}^2}{2} + \frac{p_{\varphi}^2}{2\sin^2\theta} + \frac{9g(8 - \tan^2\theta)^2}{2(3\tan^2\theta - 8 + \tan^3\theta\cos3\varphi)^2} + \frac{12g}{3\tan^2\theta - 8 + \tan^3\theta\cos3\varphi} + \frac{9g}{4\sin^2\theta(1 + \cos6\varphi)}.$$
 (14)

The invariance under the  $Z_3$  group of the rotation on  $2\pi/3$  along the third axis is apparent.

The potential (14) is really horrible. It is difficult to believe that the system with such a potential could be integrable, or could admit a separation of variables. However, the Hamiltonian can be represented in a much simpler form. Indeed, there are three pairs of the orthogonal vectors  $\mathbf{b}^{12} \cdot \mathbf{b}^{34} = \mathbf{b}^{13} \cdot \mathbf{b}^{24} = \mathbf{b}^{14} \cdot \mathbf{b}^{23} = 0$ . Taking the vector products of these pairs, one can find out that they form an orthogonal frame:

$$\mathbf{a}_1 \equiv \mathbf{b}^{12} \times \mathbf{b}^{34}, \qquad \mathbf{a}_2 \equiv \mathbf{b}^{13} \times \mathbf{b}^{24}, \qquad \mathbf{a}_3 \equiv \mathbf{b}^{14} \times \mathbf{b}^{23}: \qquad \mathbf{a}_i \cdot \mathbf{a}_j = \delta_{ij}.$$
 (15)

The vectors  $\mathbf{a}_i$  are normal to the squares of the cuboctahedron (figure 2). In this coordinate system, the Hamiltonian (4) looks like

$$\tilde{\mathcal{H}} = \sum_{i=1}^{3} \frac{p_i^2}{2} + \sum_{1 \le i < j \le 3} \left( \frac{g}{(u_i - u_j)^2} + \frac{g}{(u_i + u_j)^2} \right), \qquad \{p_i, u_j\} = \delta_{ij}, \tag{16}$$

where, again, we keep the old notations for the new momenta. This is the three-particle  $D_3$ Calogero model [20]. However, this is an expected result, since the diagrams  $D_3$  and  $A_3$ coincide and define the same algebra (in the Dynkin classification,  $D_n$  is defined for  $n \ge 4$ ). The angular part of this Hamiltonian has the following form:

$$\mathcal{I} = \frac{p_{\theta}^2}{2} + \frac{p_{\varphi}^2}{\sin^2 \theta} + \frac{4g}{\sin^2 \theta} \left[ \frac{1}{1 + \cos 4\varphi} + \frac{k - 6}{k - 8 + 8/k - k \cos 4\varphi} + \frac{4(k - 16 + 16/k)}{(k - 8 + 8/k - k \cos 4\varphi)^2} \right],$$
(17)

where

$$k = \tan^2 \theta = \frac{1 - \cos 2\theta}{1 + \cos 2\theta}.$$

In these new spherical coordinates, the invariance under  $Z_4$  rotations  $\varphi \rightarrow \varphi + \pi/4$  and spatial reflections  $\theta \rightarrow \pi - \theta$ , which are a subgroup in  $O_h$ , is transparent.

As was explained above and showed explicitly for the three-particle system,  $\mathcal{I}$  can be expressed in terms of the five integrals of the maximally superintegrable Hamiltonian (16). It seems that the two additional integrals of  $\mathcal{H}$  can be obtained from the Liouville integrals by Poisson bracket action with  $\mathcal{I}$  like in (11) for the three-particle case.

Since the spherical system (17) was obtained from the Calogero model, it is also integrable. Its constants of motion can be obtained from those of the original model.

#### 5. Summary and discussion

In conclusion, let us emphasize the main results of the current paper.

We have found that the angular part of the *N*-particle rational Calogero model (in the center-of-mass system) gives rise to the N(N-1)/2-center hyperspherical (Higgs) oscillator. Its relations with the superintegrability of the Calogero system have been discussed briefly.

For the three-particle system, we have related the angular part of the Calogero Hamiltonian (which is quadratic in momentum) to the higher-order constants of motion.

For the four-particle Calogero model, the force centers are located at the vertexes of the Archimedean solid cuboctahedron.

We are planning in future studies to investigate the reflection of the superintegrability of the rational four-particle Calogero model on the properties of the corresponding spherical system and, presumably, to extend this investigation to the case of N > 4 particles. In particular, this would help us to answer whether the Hamiltonian (17) admits a separation of variables. We expect that the Poisson bracket of the angular part with the Liouville constants of motion will generate the additional series of conserved quantities, which are responsible for the superintegrability.

Another task is to extract and study the angular parts of Calogero models associated with other Lie algebras. It is obvious that they are also connected with a multi-center spherical integrable system related to (high-dimensional) polyhedra.

It is clear that the proposed construction is applicable for the quantum spin-Calogero model too. In that case, the force centers of the angular part will be equipped by the spin-1/2 exchange interactions [36]. In this context, the relation of the four-particle system with the cuboctahedron becomes important. We expect that using the freezing trick [37], one can obtain an integrable spin lattice system on the cuboctahedron. Note that recently the Heisenberg spin systems on large magnetic molecules have been investigated intensively [38]. In particular, cuboctahedric molecular magnets with nearest-neighbor Heisenberg interaction have been obtained experimentally and studied theoretically [39]. It will be interesting to consider from this viewpoint the N = 2 supersymmetric Calogero system [40]. The construction of the  $\mathcal{N} = 4$  supersymmetric counterpart of the suggested system and the study of its integrability is also important. For the cuboctahedric system, the solution of this task is more or less obvious: we just need to check whether it is possible to represent the Hamiltonian (14) or (17) in the form [41]

$$\mathcal{I} = \frac{1}{g(z,\bar{z})} \left( \pi \bar{\pi} + \frac{F(z)\overline{F}(\bar{z})}{(1+\lambda(z)\overline{\lambda}(\bar{z}))^2} \right), \quad \{\pi, z\} = 1, \qquad \text{where} \quad \overline{\lambda}' F = -\lambda \overline{F}.$$

In this respect, the recent paper [42], where the supersymmetric Calogero model was related to the nontrivial deformation of spin-Calogero model, deserves to be mentioned.

#### Acknowledgments

We are grateful to Sergey Krivonos for discussions on the three-particle Calogero system, which prompted us to carry out this study, and to Vadim Ohanyan and Olaf Lechtenfeld for their interest in the work and useful comments. The work was supported by grants NFSAT-CRDF UC-06/07, INTAS-05-7928 (TH and AN), ANSEF-1386PS (TH), ANSEF-1730PS (AN and VY), and by the Artsakh Ministry of Education and Science (AN and TH).
