LETTER TO THE EDITOR

Estimates of configurational interactions in binary alloys from diffuse scattering data

V G Vaks, N E Zein and V V Kamyshenko I V Kurchatov Institute of Atomic Energy, Moscow 123182, USSR

Received 3 October 1988

Abstract. Previously described cluster methods are used to estimate pairwise configurational interactions V(r) in a number of binary alloys from data on the diffuse scattering of neutrons or x-rays by these alloys. The temperature dependence of the parameters V estimated from the most reliable (neutron) data appears to be rather weak. The concentration dependence for the Ni–Cu alloys studied is, in contrast, strong and unusual; this seems to be due to band-structure effects. First-principles estimates of V obtained using the coherent-potential approximation agree in order of magnitude with our V while those based on the Connolly and Williams approach, neglecting non-nearest-neighbour interactions, seem to overestimate the values of V considerably.

The development of microscopic methods for calculating the phase diagrams and stability of alloys is known to be a problem in metal physics. In the statistical theory of alloys such methods are formulated in terms of configurational Hamiltonians, including effective *n*site interactions $V^{(n)}(r_1, r_2, \ldots, r_n)$ as the main parameters of the theory; see, e.g., Khachaturian (1974), Gonis *et al* (1987). Recently several theoretical approaches for calculating $V^{(n)}$ have been suggested (see Connolly and Williams (1983), Gonis *et al* (1987), and references therein) and a number of calculations have been performed (Terakura *et al* 1987, Wei *et al* 1987, Carlsson and Sanchez 1988). However, estimates of $V^{(n)}$ obtained by different methods sometimes disagree by more than an order of magnitude (see below), so quantitative estimates of $V^{(n)}$ obtained from experiments seem to be highly desirable.

Early estimates were made by Clapp and Moss (1966, 1968). They used data on the short-range-order (SRO) parameters $\alpha(\mathbf{r}_i) = \alpha_i$, or their Fourier components $\alpha(\mathbf{k})$ (which are proportional to the intensity of the diffuse scattering with momentum transfer \mathbf{k}), and interpreted these using the high-temperature approximation for $\alpha(\mathbf{k})$ suggested earlier by Krivoglaz (1957, 1984). However, the Krivoglaz–Clapp and Moss (KCM) formula corresponds to the mean-field approximation for $\alpha(\mathbf{k})$ and can be justified only if the interactions V are much less than the temperature T. In real alloys values of V/T are often not small and can even be large, and reliance cannot be placed on estimates obtained using the KCM expression.

It has been suggested that the variational cluster field method (CFM) may be of use in calculating statistical properties of alloys with strong interactions $V \ge T$, (see Vaks *et al* (1988), to be referred to as I, and references therein). The CFM is a simplified version of the cluster variation method (Kikuchi 1951, Sanchez *et al* 1984) in which long-ranged interactions characteristic of real alloys can also readily be taken into account. The results in the CFM can be written in the form of 'cluster-cumulant' expansions in terms of the contributions of *n*-particle correlations, with increasing *n*. It was shown in I that these expansions converge rapidly at values of V characteristic of substitutional alloys. Values for pair interactions $V^{(2)}$ in the alloy Ni_{0.765}Fe_{0.235} were also estimated in I from the sRO data of Lefebvre *et al* (1981).

In this Letter we apply the CFM to estimate the interactions V in a number of other substitutional alloys, $A_{1-x}B_x$, for which SRO parameter data are available. As in I, we include in the analysis only pair interactions $V^{(2)}(r_i) = V_i$ (which can be understood as 'mixing potentials' $V(r_i) = V_i^{AA} + V_i^{BB} - 2V_i^{BB}$) and neglect many-site $V^{(n)}$ interactions as well as terms involving derivatives with respect to concentration: $\partial V_i / \partial X$, $\partial^2 V_i / \partial X^2$ (see I). Making these approximations is not essential to the method, but we have made them since only pair parameters α_i are determined in the diffuse scattering. Thus to make the 'inverse' problem of estimating V from α_i well defined we must restrict the number of unknown $V^{(n)}$ by using $V^{(2)} = V_i$. Below we show that the non-pairwise $V^{(n)}$ can also be estimated if we use some additional experimental information, e.g. that on the phase diagram. In the example considered below, including $V^{(n)} = V^{(3)}$ has a relatively small effect on values of V_i . Thus errors in our estimates of V_i due to neglecting $V^{(n)}$, $\partial V_i / \partial X$ and $\partial^2 V_i / \partial X^2$ are apparently not large.

Analysis of the available data on the diffuse scattering of neutrons or x-rays by singlecrystal disordered alloys shows that quantitative information on V_i is at present obtained mainly from neutron scattering data, such as those given by Vrijen and Radelaer (1978) for Ni_{1-x}Cu_x, Lefebvre *et al* (1981) for Ni₃Fe and Schweika (1985) for Ni₈₉Cr₁₁. The accuracy of the determination of α_i in the x-ray experiments (e.g. by Chen *et al* (1979) for Cu₃Au, Metcalfe and Leake (1975) for CuAu and Epperson *et al* (1978) for Cu_{1-x}Al_x) seems to be much lower. This is indicated by both significant violations of the normalising conditions $\alpha_0 = 1$ in these data and sharp variations of α_i and the corresponding V_i with temperature or concentration (see table 1).

As was discussed in I, and earlier by Krivoglaz (1957, 1984), the most convenient form for microscopic analysis of the SRO data is that for the quantity $\alpha^{-1}(k)$:

$$\frac{1}{\alpha(k)} = \sum_{i} a_{i} \exp(i\mathbf{k} \cdot \mathbf{r}_{i})$$
(1)

where the sum is taken over all crystal lattice vectors \mathbf{r}_i . Unfortunately, in most of the experimental work only Cowley–Warren parameters α_i are presented. Since the α_i (unlike the a_i in (1)) decrease very slowly with the increase of r_i , a great number of α_i are needed to describe the data, and values of α_i with large r_i usually have low accuracy. Because of this, we applied an iterative procedure to estimate a_i from the experimental α_i . This algorithm is stable and rapidly convergent for 'good', intrinsically consistent neutron data but is not so good for the less accurate α_i obtained from the x-ray experiments. Therefore, estimates for the alloys Ni–Fe, Ni–Cr and Ni–Cu in table 1 are much more reliable than those for Cu–Au and Cu–Al.

With the known a_i , values of V_i were found by the method described in I for the alloy Ni₃Fe. We used the most accurate ' $\tilde{\sigma}$ -approximation' including about 30 different types of cluster—in particular, six-site ones. The convergence of the cluster-cumulant expansion used was usually as rapid as in the case discussed in I.

The estimates obtained for the V_i are presented in table 1 and in figure 1. It is firstly seen that for the 'reliable' data (for Ni₃Fe and Ni–Cu alloys) the variation of the main

constants V_1 and V_2 with T is usually small. This seems natural, since the dependence on T of V_i can, generally, arise only from small effects, such as the thermal expansion, the thermal smearing of the Fermi surface and so on. The constant V_2 in Ni₃Fe changes significantly between T = 958 K and T = 808 K, but it can be connected with ferromagnetic ordering at T = 823 K. It is also seen that the small V_i with $i \ge 4$ as well as the V_i estimated from the x-ray data often vary significantly with T. This seems to reflect mainly the larger experimental errors for these particular V_i . Therefore, values of V_i for the alloys Cu–Au and Cu–Al in table 1 should be regarded only as order-of-magnitude estimates while the estimates for the systems Ni–Fe, Ni–Cr and Ni–Cu can be treated as quantitative.

The values of V_1 and V_2 for Ni₃Fe and Ni₈₉Cr₁₁ given in table 1 are similar, which apparently corresponds to the similarity of the Fe and Cr properties. It is also seen that the values of V_i in the ordering alloys Ni–Fe, Ni–Cr and Cu–Au differ qualitatively from those for the decaying Ni–Cu alloys.

Figure 1. The concentration dependence of the interaction constants V_1 and V_2 in the alloys Ni_{1-x}Cu_x at different temperatures *T*. Curves A, B, C and D correspond to T = 723, 773, 873 and 973 K, respectively.

The concentration dependence of α_i was carefully investigated by Vrijen and Radelaer (1978) for Ni–Cu alloys. The corresponding $V_i(x)$ are displayed in figure 1 and in table 1. The prominent feature of the results is a sharp variation of $V_i(x)$ for $x \approx 0.5-0.6$ while for other values of x the dependence on x is weak or moderate. These results confirm qualitatively recent first-principles estimates given by Gonis et al (1987), who found similar sharp variations in the V_i with the position of the Fermi level for the model of the alloy Pd–V. The concentrational anomaly in figure 1 correlates with the change in the character of the band structure of the alloys Ni_{1-x}Cu_x for $x \sim x_c \approx 0.6$ discussed by Stocks *et al* (1971) and Gordon *et al* (1981): for $x > x_c$ the Fermi level leaves the d band. Thus the anomaly found in the $V_i(x)$ dependence seems to be one more manifestation of the strong band-structure effects in the lattice properties discussed by a number of authors, e.g. De Camargo et al (1987) and Vaks and Trefilov (1988). A search for similar anomalies in $\alpha_i(x)$ and $V_i(x)$ in other systems with band-structure anomalies (for example, in the alloys $Li_{1-x}Mg_x$ near $x_c = 0.19$ (Vaks and Trefilov 1988), $Ag_{1-x}Pd_x$ or $Nb_{1-x}Mo_x$ near $x_c = 0.4$ (Stocks *et al* 1973, De Camargo *et al* 1987)) would probably be interesting.

The values obtained for the V_i can be used for estimation of the ordering temperatures T_c . In figure 2 we present such estimates for the alloys $Ni_{1-x}Fe_x$ near x = 0.25. Supposing the values of V_i in the second row of table 1 to be independent of both the ordering and concentration (curves B in figure 2), we obtain a reasonable agreement with the experiment as regards values of T_c . However, the concentration dependence of these $T_c(x)$ differs noticeably from the observed one. In this connection we tried to estimate non-pairwise interactions of nearest neighbours $V_{NN}^{(n)}$, which should be added to pair-concentration-independent V_i to describe both the experimental α_i in Ni_{0.765}Fe_{0.235} and

Figure 2. Temperatures $T_c(x)$ for the ordering L_{12} (of the Cu_3Au type) in the alloys $Ni_{1-x}Fe_x$. Curve A: experimental data from Van Deen and Van der Woude (1981); curve B, $T_c(x)$ calculated using interaction constants from the second row of table 1; curve C: the same with the constants from the fifth row of table 1.

the character of the concentration dependence of $T_c(x)$ near its maximum. This can be achieved at $V_{\rm NN}^{(3)} = -250$ K and for the V_i indicated in the fifth row of table 1. The corresponding $T_c(x)$ are shown by curves C in figure 2. Effects of the four-site interaction $V_{\rm NN}^{(4)}$ on $T_c(x)$ are much weaker than those of $V_{\rm NN}^{(3)}$. For example, at $V^{(3)} = 0$ we should use a much larger value $V_{\rm NN}^{(4)} \approx 5000$ K to obtain a $T_c(x)$ similar to curves C. These estimates illustrate a possible scale of the non-pairwise potentials $V^{(n)}$ in Ni₃Fe. Comparison of the fifth and second rows of table 1 also shows that including $V^{(3)} \neq 0$ does not significantly change the estimates of pairwise V_i .

Let us now compare the values of V_i given in table 1 with their first-principles estimates. Gonis *et al* (1987) used cluster approaches based on the coherent-potential approximation and estimated the V_i for the alloy Pd–V to be $|V_1| \leq 300$ K, $|V_2| \leq 30$ K. This agrees in order of magnitude with the estimates in table 1. On the other hand, estimates using the Connolly and Williams (1983) approach seem to overestimate the values of V_1 considerably. For example, for the alloy Cu–Au Terakura *et al* (1987) found $V_1 > 10^4$ K (their v_2 is related to our V_1 by $V_1 = 4v_2$) which disagrees sharply with our estimates from the sR0 data. One of the causes of the discrepancy might be the neglect in their approach of the non-nearest-neighbour interactions which, according to our estimates, are quite important for the ordering energies. For example, if we put $V_i = 0$ for all i > 1 in the second row of table 1 we obtain $T_c^{calc} = 310$ K, i.e. we underestimate T_c by more than twice. Thus, taking into account the non-nearest-neighbour interactions appears necessary for obtaining realistic estimates of configurational interactions in alloys.

The authors are much indebted to V I Goman'kov and A S Steinberg for valuable information on the experimental data.
