Received March 8, 1971

Under high pressure, rutile transforms into a structure of the  $\alpha$ -PbO<sub>2</sub> type. In a previous paper (1) we proposed a simple mechanism for this transformation which is illustrated in Fig. 1. We now suggest similar cation displacements to interconvert the Li<sub>2</sub>ZrF<sub>6</sub>, trirutile, Na<sub>2</sub>SiF<sub>6</sub> and columbite structure types.

When Li<sub>2</sub>NbOF<sub>5</sub> was reported (2) as being isostructural with Li<sub>2</sub>ZrF<sub>6</sub> (3), a picture was made showing its relation to the rutile structure. In Figs. 2a and b, the structures of trirutile and Li<sub>2</sub>NbOF<sub>5</sub> are compared; Fig. 3 shows how the Li<sub>2</sub>ZrF<sub>6</sub> structure type can transform into the trirutile type if 50% of the cations are shifted in the way

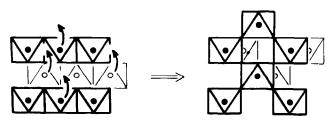

Fig. 1. The rutile structure (upper left) is compared with the  $\alpha$ -PbO<sub>2</sub> structure type (upper right). Below is shown a possible mechanism for the rutile  $\rightarrow \alpha$ -PbO<sub>2</sub> transformation. Cation movements are indicated with arrows.

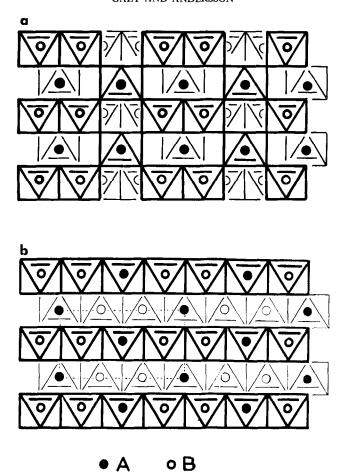

Fig. 2. In (a) the Li<sub>2</sub>ZrF<sub>6</sub> structure type (Li<sub>2</sub>NbOF<sub>5</sub>) is given. In (b) the trirutile structure of the composition AB<sub>2</sub>X<sub>6</sub>. In both the structures, A corresponds to filled circles, and open circles are the B-atoms.

indicated by the curved arrows, and without disorder. To our knowledge, no such transformation has been reported for the compounds  $\text{Li}_2\text{NbOF}_5$  and  $\text{Li}_2\text{ZrF}_6$ . However,  $\alpha\text{-Li}_2\text{SnF}_6$  of the  $\text{Li}_2\text{ZrF}_6$  type has been found to transform to a structure of the trirutile type, designated  $\beta\text{-Li}_2\text{SnF}_6$  at 510°C (4).

Another interesting transformation was reported recently (5, 6). At about  $400^{\circ}$ C,  $\alpha$ -Li<sub>2</sub>GeF<sub>6</sub>, of the trirutile type, transforms to  $\beta$ -Li<sub>2</sub>GeF<sub>6</sub> which has the Na<sub>2</sub>SiF<sub>6</sub> type structure (7). Figure 4 shows the Na<sub>2</sub>SiF<sub>6</sub> structure projected along the c-axis, and Fig. 5 the trirutile structure in an analogous projection. The geometrical relation between these structures can be shown by considering the Na<sub>2</sub>SiF<sub>6</sub> type. The cations in the octahedra drawn with heavy lines are at  $z = \frac{1}{2}$ , those in the lighter octahedra at z = 0. If the metal atoms at z = 0 in m-planes move

to  $z=\frac{1}{2}$ , and those at  $z=\frac{1}{2}$  in *n*-planes to z=0, the trirutile structure is obtained. This involves half the cations passing through octahedral faces along half the *c*-axis; the anion lattice remains intact. If the A and B atoms keep their relative order during the transformation, the ordered Na<sub>2</sub>SiF<sub>6</sub> structure type may, in the reverse way, be geometrically derived directly from the ordered trirutile type. That  $\beta$ -Li<sub>2</sub>SnF<sub>6</sub> and  $\beta$ -Li<sub>2</sub>GeF<sub>6</sub> are formed as ordered compounds, with, respectively, the trirutile and Na<sub>2</sub>SiF<sub>6</sub> structures, indicates that the geometrical proposals described here may very well be correct mechanisms.

All these compounds have approximately the same (hexagonally close packed) anion arrangement. At very high pressures the preferred cation arrangement seems to be like that in the  $\alpha$ -PbO<sub>2</sub>

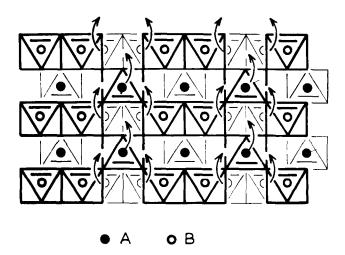

Fig. 3. If cations are shifted in the way described by arrows, the trirutile structure is formed from the Li<sub>2</sub>ZrF<sub>6</sub> structure type.

structure type. Amongst the ternary compounds of general formula  $AB_2X_6$  a similar arrangement of (ordered) cations occurs in columbite FeNb<sub>2</sub>O<sub>6</sub>. By analogy with the rutile  $\rightleftarrows \alpha$ -PbO<sub>2</sub> transformation,

we might therefore expect the  $AB_2X_6$  compounds discussed above to transform at high enough pressures to a ternary analog of  $\alpha\text{-PbO}_2$ , possibly with the cations ordered as in FeNb<sub>2</sub>O<sub>6</sub>.

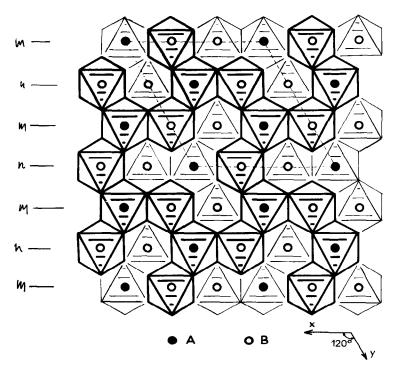

Fig. 4. The Na<sub>2</sub>SiF<sub>6</sub> structure type.

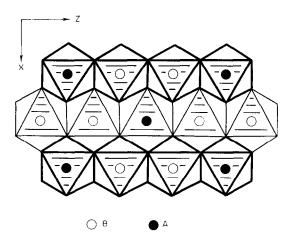

Fig. 5. The trirutile structure type.

It would be interesting to study the effects of applied pressure in the high temperature experiments referred to above.

In the meantime a tentative pressure-temperature phase diagram is given in Fig. 6. Its construction is based on the observations that

- (a)  $\alpha$ -LiSnF<sub>6</sub> transforms to  $\beta$ -Li<sub>2</sub>SnF<sub>6</sub>,
- (b)  $\alpha$ -Li<sub>2</sub>GeF<sub>6</sub> transforms to  $\beta$ -LiGeF<sub>6</sub> at high temperatures and
- (c) rutile transforms to a structure of the α-PbO<sub>2</sub> type at high pressure.
