#### Abstract

We have studied the preparation and crystallographic structure of three perovskite-type compounds: $\mathrm{Sr}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$, cubic, the lattice parameter of which is $a=7.812 \AA ; \mathrm{Ca}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$, tetragonal, the lattice parameters of which are $a=5.408 \AA$ and $c=7.635 \AA$; and $\mathrm{Ba}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$, hexagonal, the lattice parameters of which are $a=5.691 \AA$ and $c=13.957 \AA$. We have compared these three structures and shown the relationship between the dimensions of the alkaline-earth metal and the existence of the different structures.

## Introduction

In the continuation of our work about perovskite type compounds, the formula of which is $\mathrm{A}_{3} \mathrm{BB}_{2}^{\prime} \mathrm{O}_{9}$, we report here the preparation and structure of three new phases, $\mathrm{Sr}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}(1), \mathrm{Ca}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$, and $\mathrm{Ba}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$. The last phase has been mentioned by Ward (2).

We have reported before (1) the method used in preparing $\mathrm{Sr}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$ and its probable structure. In a continuation of this work, we report the preparation and structural study of $\mathrm{Ca}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$ and $\mathrm{Ba}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$. Then we will compare the different structures of $\mathrm{Sr}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}, \mathrm{Ca}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$, and $\mathrm{Ba}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$.

## Preparation Process of $\mathbf{C a}_{3} \mathbf{C r}_{2} \mathbf{W O}_{9}$ and $\mathrm{Ba}_{3} \mathrm{Cr}_{2} \mathbf{W O}_{9}$

The method used for preparing $\mathrm{Ca}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$ and $\mathrm{Ba}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$ is the same as that employed for $\mathrm{Sr}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$ (1). Mixtures of $\mathrm{Ca}_{3} \mathrm{WO}_{6}$ and $\mathrm{Cr}_{2} \mathrm{O}_{3}$ or $\mathrm{Ba}_{3} \mathrm{WO}_{6}$ and $\mathrm{Cr}_{2} \mathrm{O}_{3}$ are ground and heated in evacuated quartz ampoules, between 1150 and $1200^{\circ} \mathrm{C}$. The vacuum must reach $10^{-6} \mathrm{mmHg}$. Thus, the single phases $\mathrm{Ca}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$ and $\mathrm{Ba}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$ are obtained.

$$
\begin{aligned}
& \mathrm{Ca}_{3} \mathrm{WO}_{6}+\mathrm{Cr}_{2} \mathrm{O}_{3} \rightarrow \mathrm{Ca}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9} \\
& \mathrm{Ba}_{3} \mathrm{WO}_{6}+\mathrm{Cr}_{2} \mathrm{O}_{3} \rightarrow \mathrm{Ba}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}
\end{aligned}
$$

We check, by X ray diffraction powder diagrams, that the phases are well crystallized, and that they do not contain any additional compound.

It is also possible to heat the mixtures in a helium atmosphere furnace, the helium being purified by passing on zirconium rolls heated at $700^{\circ} \mathrm{C}$, so that the gas loses even the smallest trace of oxygen (3).

## Structures Determination

Lattice parameters and X ray diffraction intensities were obtained from a Philips diffractometer, using $\mathrm{Co} \mathrm{K}_{\alpha}$ radiation. For the parameters determination, we used a leastsquares fit of the data on an UNIVAC 1110 computer, by Taupin's method (4). The scattering factors are obtained by Cromer's method (5).
(a) $\mathrm{Sr}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$

By the least-square refinement we found the lattice parameter in cubic system to be $a=7.812 \pm 0.001 \AA$. X ray intensity data fit with the space-group Fm3m (6), the positions of which are reported in Table I. Chromium and tungsten may be completely or partially ordered on the $4 a$ and $4 b$ positions,

$$
\mathrm{M}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}(\mathrm{M}=\mathrm{Sr}, \mathrm{Ca}, \text { or } \mathrm{Ba})
$$

TABLE I
Wyckoff Positions of the Space Group Fm3m

| Ions | Wyckoff <br> notations | Wyckoff positions <br> (translation 0, $\left.\frac{1}{2}, \frac{1}{2}\right) \mathbb{2}$ |
| :---: | :---: | :---: |
| Sr | $8 c$ | $\pm\left(\frac{1}{2}, \frac{1}{4}, \frac{1}{4}\right)$ |
| $\mathrm{Cr}, \mathrm{W}$ | $4 b$ | $\frac{1}{2}, \frac{1}{2}, \frac{1}{2}$ |
| $\mathrm{Cr}, \mathrm{W}$ | $4 a$ | $0,0,0$ |
| O | $24 e$ | $\pm(0,0, x) \mathbb{2}$ |

and we may represent $\mathrm{Sr}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$ by a general formula:

$$
\mathrm{Sr}_{3}\left[\mathrm{Cr}_{(3 / 2-\lambda)} \mathrm{W}_{\lambda}\right]_{4 b}\left[\mathrm{Cr}_{(1 / 2+\lambda)} \mathrm{W}_{(1-\lambda)}\right]_{4 a} \mathrm{O}_{9}(l)
$$

Refinement on the computer yielded the order parameter $\lambda=0.28$ and the atomic parameter $x=0.242$. These values give a good agreement between experimental intensities and calculated ones ( $R=0.05$ ).

## (b) $\mathrm{Ca}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$

Using Taupin's program (4), we calculated the lattice parameters of $\mathrm{Ca}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$ on the basis of a tetragonal cell: $a=5.408 \pm 0.001 \AA$ and $c=7.635 \pm 0.001 \AA$. Comparing the $X$ ray powder patterns of $\mathrm{Ca}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$ and $\mathrm{Sr}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$, we have considered the $\mathrm{Ca}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$ cell to be pseudocubic and its structure is issued from the distortion of the Fm3m cell that we studied in last paragraph. The space-group theory allows us to know which space group the tetragonal structure of $\mathrm{Ca}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$ will belong (7).

From the point group m3m, we get, after substracting certain symmetry elements the seven tetragonal point group. The matrix

$$
\left|\begin{array}{ccc}
1 / 2 & \overline{1} / 2 & 0 \\
1 / 2 & 1 / 2 & 0 \\
0 & 0 & 1
\end{array}\right|
$$

gives the $h, k, 1$ indexes of the lattice in the tetragonal unit cell, from the $h, k, 1$ in the cubic unit cell. In the tetragonal system, we obtain a body centered cell.

The matrix $\mathbf{M}^{\prime}$, reciprocal and reverseordered of $\mathbf{M}$ :

$$
\left|\begin{array}{lll}
1 & \overline{1} & 0 \\
1 & 1 & 0 \\
0 & 0 & 1
\end{array}\right|
$$

gives the Wyckoff positions in the tetragonal system. Hence, we find the Wyckoff positions of two tetragonal space groups I422 and I4/ mmm . We have reported in Table II the Wyckoff positions of the Fm3m space group, and correspondingly, the Wyckoff positions of the tetragonal space group.

The cell being centrosymmetric, we based our calculation on the $14 / \mathrm{mmm}$ space group. Refinement on the computer gave the atomic parameters $x=z=0.260$ (with $R=0.06$ ), chromium and tungsten being completely ordered on the Wyckoff positions $a$ and $b$.

## (c) $\mathrm{Ba}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$

The lattice parameters were obtained on the basis of the hexagonal system: $a=5.691 \pm$ $0.002 \AA$ and $c=13.957 \pm 0.01 \AA$. Comparing

| $(\mathrm{Fe}, \mathrm{Te})$ | $4 f$ | $\frac{1}{3}, \frac{2}{3}, z ; \ldots$ |
| $\mathrm{O}_{\mathbf{1}}$ | $6 h$ | $x, 2 x, \frac{1}{4} ; \ldots$ |
| $\mathrm{O}_{\mathbf{I I}}$ | $12 k$ | $x, 2 x, z ; \ldots$ |

TABLE IV
Atomic Parameters of $\mathrm{Ba}_{\mathbf{3}} \mathrm{Cr}_{\mathbf{2}} \mathrm{WO}_{\mathbf{9}}$

| Ions | Wyckoff notation | Parameters |
| :---: | :---: | :---: |
| Ba | $4 f$ | $z=0.122$ |
| $(\mathrm{~W}, \mathrm{Cr})$ | $4 f$ | $z=0.833$ |
| O | $6 h$ | $x=0.530$ |
| O | $12 k$ | $z=-0.018 ; x=0.878$ |

this to $\mathrm{Ba}_{3} \mathrm{Fe}_{2} \mathrm{TeO}_{9}(8)$, we observed that $\mathrm{Ba}_{3} \mathrm{Fe}_{2} \mathrm{TeO}_{9}$ and $\mathrm{Ba}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$ were isostructural, with a $\mathrm{BaTiO}_{3}$ isotypic cell. Then we used the space group $\mathrm{P6}_{3} / \mathrm{mmc}$ to solve the structure. The Wyckoff positions of this space group are reported in Table III. The general formula of $\mathrm{Ba}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$ is $\mathrm{Ba}_{6}\left[\mathrm{Cr}_{(2-y)} \mathrm{W}_{y}\right]_{2 a}$ $\left[\mathrm{Cr}_{(2+y)} \mathrm{W}_{(2-y)}\right]_{4 \rho} \mathrm{O}_{18}$, where $0 \leqslant y \leqslant 2$. The best solution, obtained by square refinement, led to the atomic parameters reported in Table IV, with $R=0.05$.

## Discussion of the Structures

By replacing strontium by calcium and barium, we notice: (1) the tetragonal deformation of the cubic cell, when strontium is replaced by calcium; and (2) the hexagonal perovskite structure, when strontium is replaced by barium.

Note that the different structures of these three compounds could be imagined by considering the perovskite structure existence diagram (Fig. 1), established by Poix (9). In this diagram, the existence areas of the different perovskite structures are represented:
the cubic, the orthorhombic, and the hexagonal. Coordinates are the distance $\beta=[\mathrm{Me}-\mathrm{O}]_{6}$, the metal-oxygen distance in the sixfold coordination, and $\theta=[\mathrm{Me}-\mathrm{O}]_{12}$, the metaloxygen distance in the twelve coordination. $\beta$ and $\theta$ are characteristics of atoms (10,11). The different areas are determined by the Goldschmidt factor $t=\theta /(\beta \sqrt{ } 2)$, and the curve $\theta=0.406 \beta^{2}+2.165 \beta$ (9).

In our case, we obtain:

$$
\begin{aligned}
\theta_{1} & =[\mathrm{Sr}-\mathrm{O}]_{12}=2.775 \AA \\
\theta_{2} & =[\mathrm{Ca}-\mathrm{O}]_{12}=2.669 \AA \\
\theta_{3} & =[\mathrm{Ba}-\mathrm{O}]_{12}=2.886 \AA \\
\beta & =\left(2[\mathrm{Cr}-\mathrm{O}]_{6}+[\mathrm{W}-\mathrm{O}]_{6}\right) / 3=1.958 \AA .
\end{aligned}
$$

In the case of $\mathrm{Sr}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$, we obtain the point A , the coordinates of which are $\beta=$ 1.958 and $\theta_{1}=2.775$, which is placed in the cubic area. In the case of $\mathrm{Ca}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$, we obtain a point $B$, the coordinates of which are $\beta=1.958$ and $\theta_{2}=2.669$, placed in the orthorhombic area, at the border line of the cubic one. This is why we found a tetragonal structure, and not an orthorhombic one, since the deformation of the cubic structures is light.

$$
\mathrm{M}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}(\mathrm{M}=\mathrm{Sr}, \mathrm{Ca}, \text { or } \mathrm{Ba})
$$

Fig. 1. Existence areas of the different perovskite structures.

Fig. 2. (a) Arrangement of oxygen octahedrons in $\mathrm{Sr}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$ cell. (b) Arrangement of oxygen octahedrons in $\mathrm{Ba}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$ cell.

In fact, the deformation of the Fm 3 m structure is not sufficient to bring an orthorhombic structure. (For example, Pbnm , issued from Fm3m by subtracting more symmetry elements). In the case of $\mathrm{Ba}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$, we obtain a point C , the coordinates of which are $\theta_{3}=$ 2.886 and $\beta=1.958$, placed in the hexagonal area.

We may also observe, that the arrangement of the oxygen octahedrons are not the same in the case of $\mathrm{Sr}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$ and $\mathrm{Ca}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$ (Fig. 2a), and in the case of $\mathrm{Ba}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$ (Fig. 2b) (8).

## Conclusion

The three perovskite type phases $\mathrm{Sr}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}, \mathrm{Ca}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$, and $\mathrm{Ba}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$ are examples of three different perovskite type structures, cubic, tetragonal, and hexagonal. The dimension of the alkaline-earth metal is directly related with every different structure. The space group $14 / \mathrm{mmm}$, to which $\mathrm{Ca}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$ belongs, is issued from the space group Fm3m by subtracting certain symmetry elements. Differently, $\mathrm{Ba}_{3} \mathrm{Cr}_{2} \mathrm{WO}_{9}$ belongs
to the space group $\mathrm{P} 6 / 3 \mathrm{mmc}$, which is not a subgroup of Fm3m, and the arrangement of oxygen octahedrons is different.
