*Neutron Powder Diffraction and Magnetic Measurements on RbTi<sub>3</sub>, RbVI<sub>3</sub>, and CsVI<sub>3</sub>.* H. W. ZANDBERGEN, Gorlaeus Laboratories, University of Leiden, P.O. Box 9502, 2300 RA Leiden, The Netherlands. CsVI<sub>3</sub> ( $a = 8.124(1)$ ,  $c = 6.774(1)$  Å,  $Z = 2$ ,  $P6_3/mmc$  at 293 K) adopts the BaNiO<sub>3</sub> structure. Three-dimensional magnetic ordering takes place at  $T_c = 32(1)$  K. At 1.2 K the magnetic moment is  $1.64(5) \mu_B$  and it forms a  $120^\circ$  spin structure in the basal plane. RbVI<sub>3</sub> ( $a = 13.863(2)$ ,  $c = 6.807(1)$  Å,  $Z = 6$ ,  $P6_3cm$  or  $P\bar{3}c1$  at 293 K) and RbTi<sub>3</sub> ( $a = 14.024(3)$ ,  $c = 6.796(2)$  Å,  $Z = 6$ ,  $P6_3cm$  or  $P\bar{3}c1$  at 293 K) adopts a distorted BaNiO<sub>3</sub> structure, probably isostructural with KNiCl<sub>3</sub>.  $T_c$  of RbVI<sub>3</sub> is  $25(1)$  K. At 1.2 K, RbVI<sub>3</sub> has a spin structure similar to the one of CsVI<sub>3</sub> with a magnetic moment of  $1.44(6) \mu_B$ . RbTi<sub>3</sub> shows no magnetic ordering at 4.2 K. It is shown that a deviation from the  $120^\circ$  structure is expected for compounds with a distorted BaNiO<sub>3</sub> structure such as RbVI<sub>3</sub>. The cell dimensions of CsTi<sub>3</sub> are reported.

*The Resistivity and Magnetic Susceptibility of V<sub>3</sub>O<sub>5</sub> Single Crystals.* H. JHANS AND J. M. HONIG,\* Department of Chemistry, Purdue University, West Lafayette, Indiana 47907. New resistivity studies on single-crystal V<sub>3</sub>O<sub>5</sub> show that the phase transformation at 427 K involves an insulator-metal transition; the resistivities reported here lie somewhat below those cited in numerous earlier investigations. Magnetic susceptibility ( $\chi$ ) measurements exhibit only very small changes at the transition. It is pointed out that the maximum in  $\chi$  at 125 K should be correlated with the onset of antiferromagnetic ordering near 76 K.

*Forces de la Liaison Te-O: Coordination et Localisation de la Paire Libre de l'Atome de Tellure IV dans les Tellurites.* E. PHILIPPOT, Laboratoire de Chimie Minerale C, Université des Sciences et Techniques du Languedoc, Place Eugene Bataillon, 34060 Montpellier, France. The calculation of bond valences ( $S$ ) from the bond lengths ( $R$ ) observed in many accurate structure determinations of tellurites, Te<sup>IV</sup>, using the relation  $S = S_0(R/R_0)^{-N}$ , allows us to refine the  $R_0$  and  $N$  values proposed by Brown. If we classify the different TeO <sub>$y$</sub>  surroundings by taking into account the three strongest bond valences in their relation to the weakest one, it can be verified that the observed variation allows us to foresee the atomic coordination of tellurium IV atom with respect to the other components of the structure. On the other hand, the probable location of the lone pair  $5s^2$  of tellurium IV atom can be related to the evolution of its coordination.

*Bidimensional Magnetic Properties of  $\beta$ -Sr<sub>2</sub>MnO<sub>4</sub>.* J. C. BOULOUX, J. L. SOUBEYROUX, G. LE FLEM,\* AND P. HAGENMULLER, Laboratoire de Chimie du Solide, Université de Bordeaux I, 351 cours de la Liberation, 33405 Talence, France.  $\beta$ -Sr<sub>2</sub>MnO<sub>4</sub> belongs to the K<sub>2</sub>NiF<sub>4</sub>-type structure. The magnetic structure studied by neutron diffraction is characterized by antiferromagnetic interactions between nearest-neighbor Mn<sup>4+</sup> ions. The value of the exchange integral  $J/k$  calculated by the high-temperature series expansion method is about  $-80$  K. All magnetic properties of  $\beta$ -Sr<sub>2</sub>MnO<sub>4</sub> show the two-dimensional character of the magnetic interactions and illustrate the strong covalency of the Mn-O bonds within the magnetic layers.

*Le Système BaFeO<sub>2.50</sub>-BaZnO<sub>2</sub>.II. Conductivité Mixte et Autres Propriétés Physiques.* P. NEU, M. ZANNE, C. GLEITZER,\* AND G. DUDLEY, Laboratoire de Chimie du Solide Minéral, Université de Nancy I, 54037 Nancy, France. The  $\alpha$  phase, perovskite type, BaFe <sub>$1-x$</sub> Zn <sub>$x$</sub> O <sub>$2.5-r/2$</sub>  ( $0.05 < x < 0.40$ ), shows weak ferrimagnetism for  $x < 0.25$ , with  $T_c$  around  $470^\circ\text{C}$ , and paramagnetism (above 77 K) for  $x > 0.25$ , which means progressive destruction of the antiferromagnetic order observed in BaFeO<sub>2.5</sub>. The  $\beta$  (Ba<sub>4</sub>Fe<sub>2</sub>Zn<sub>2</sub>O<sub>9</sub>) and  $\gamma$  (BaZn <sub>$1-y$</sub> Fe <sub>$y$</sub> O <sub>$2+y/2$</sub> ) phases present properties in agreement with a strong perturbation of the perovskite octahedral site. The electrical conductivity is rather high, of mixed character, with a differing ionic-electronic distribution, depending on the synthesis conditions and on the temperature, due to different activation energies. The oxygen diffusion
