A Study of Infrared Absorption in the Oxidation of Zinc-Substituted Magnetites to Defect Phase  $\gamma$  and Hematite. B. GILLOT,\* R. M. BENLOUCIF, AND A. ROUSSET, Laboratoire de Recherches sur la Réactivité des Solides, Faculte des Sciences Mirande, B.P. 138, 21004 Dijon Cedéx, France. The effect of substitution extent on formation of superstructure-ordered vacancies in zinc-substituted lacunar spinels of type  $Zn_2^{++}Fe_{3+x}^{+})_A(Fe_{3+x}^{+})_{3}\Box_{(1-x)/3}BO_4^{2-}$  was investigated using ir spectrometry. Only those lacunar phases whose substitution extent x is less than about 0.3 show a vacancy ordering on octahedral sites. In addition, referring to the disappearance of the 635-cm<sup>-1</sup> absorption band, which is characteristic of these lacunar spinels, we show that the transformation temperature of the  $\gamma$  phases into  $\alpha Fe_2O_3$  increases with zinc substitution extent. For the  $\alpha$  phases obtained at 700°C we have found a linear variation between the intensity difference of the 390- and 450-cm<sup>-1</sup> absorption bands and the percentage of  $\alpha Fe_2O_3$ .

Donnees cristallographiques sur une nouvelle serie de manganites mixte de terre rare et d'alcalinoterreux. M. N. DESCHIZEAUX CHERUY\* AND J. C. JOUBERT, Laboratoire de Matériaux, Section Génie Physique, ENS-IEG, Domaine Universitaire B.P. 46, 38402 St. Martin d'Heres, France. The synthesis of two new series of oxides:  $BaLn_2Mn_2O_7$  and  $SrLn_2Fe_2O_7$ , where Ln is a rare earth, was performed. The experimental conditions are given along with some crystal data. The diffraction patterns show a close resemblance with those of the double-perovskite-block compounds  $BaLn_2Fe_2O_7$  and  $SrLn_2Fe_2O_7$ . However, the c/a ratio of the tetragonal cell is somewhat larger for the manganese compounds than for the iron compounds, due to a Jahn-Teller distortion of the  $Mn^{3+}O_6$  octahedral sites.

The Crystal Structure of Barium Manganese(II) Iron(III) Fluoride BaMnFeF<sub>7</sub>. H. HOLLER, D. BABEL\*, M. SAMOUËL, AND A. DE KOZAK. Sonderforschungsbereich 127 and Fachbereich Chemie der Philipps-Universität, Hans-Meerwein-Strasse, D3550 Marburg, West Germany. The crystal structure of the monoclinic compound BaMnFeF<sub>7</sub> has been determined:  $a = 553.2(1), b = 1098.0(2), c = 918.3(1) \text{ pm}, \beta = 94.67(1)^\circ, V = 555.9(3) \times 10^{-24} \text{ cm}^3, Z = 4$ . All atoms are in general positions of space group  $P2_1/c$ , weighted R = 0.031, using 1771 independent single-crystal reflections with  $I > 2\sigma(I)$ . The structure consists of edge-sharing dinuclear Mn<sub>2</sub>F<sub>10</sub><sup>6</sup> units (Mn-Mn = 322.2 pm), linked via corners by intermediate FeF<sub>6</sub> octahedra, at which two *cis* ligands remain unbridged. The average distances in the distorted octahedra are Mn-F = 211.6 pm and Fe-F = 192.7 pm. The barium atoms are irregularly 12-coordinated with a mean distance Ba-F = 290.5 pm. The structure is discussed in relation to the trigonal weberite Na<sub>2</sub>MnFeF<sub>7</sub> and others.

Electrical Conductivity in Strontium Titanate. U. BALACHANDRAN AND N. G. EROR<sup>\*</sup>, Oregon Graduate Center, Beaverton, Oregon 97006. The electrical conductivity of polycrystalline SrTiO<sub>3</sub> was determined for the oxygen partial pressure range of  $10^{0}-10^{-22}$  atm and temperature range of 800 to 1050°C. The data were found to be proportional to the -1/6th power of the oxygen partial pressure for the oxygen pressure range  $10^{-5}-10^{-22}$  atm, proportional to  $P_{0_2}^{-1/4}$  for the oxygen pressure range  $10^{-8}-10^{-15}$  atm, and proportional to  $P_{0_2}^{-1/4}$  for the oxygen pressure range  $10^{-8}-10^{-15}$  atm, and proportional to  $P_{0_2}^{-1/4}$  for the oxygen pressure range  $10^{-8}-10^{-15}$  atm, the presence of very small amounts of acceptor impurities in SrTiO<sub>3</sub>.

New Ternary Molybdenum Chalcogenides  $M_{1+x}Mo_6Se_8$ , with M = Np, Pu, Am. C. H. DE NOVION<sup>\*</sup>, D. DAMIEN, AND H. HUBERT, SESI, Bâtiment 31, CERN B.P. n<sup>0</sup>6, 92260 Fontenay-aux-Roses, France. The ternary molybdenum selenides  $An_{1.0}Mo_6Se_8$  and  $An_{1.2}Mo_6Se_8$  (An = Np, Pu, Am) have been synthetized, and characterized by X-ray powder diffraction. They crystallize in the rhombohedral system and are isomorphous to the corresponding rare-earth compounds. The magnetic susceptibilities and electrical resistivities of the Pu- and Am-based compounds have been measured: the actinide ions are found to be trivalent in both compounds. No superconducting transition was found for  $Pu_{1+x}Mo_6Se_8$  and  $Am_{1+x}Mo_6Se_8$  down to 2.5 and 3.5 K respectively, contrary to the case of  $Np_{1+x}Mo_6Se_8$  for which  $T_c = 5.6$  K. The reasons of this different behavior are discussed.
