#### Abstract

$\mathrm{Bi}_{2} \mathrm{Mo}_{2} \mathrm{O}_{9}$ is monoclinic; space group $P 2_{1} / n$ with $a=11.972(3) \AA, b=10.813(4) \AA, c=11.899(2), \beta=$ $90.13(2)$, and $Z=8$. The structure was solved by Patterson and Fourier techniques. The final agreement factors of the refinement based on 2711 independent reflections were $R=0.051$ and $R_{w}=0.057$. Based on the structure, the formula may be represented as $\mathrm{Bi}\left(\mathrm{Bi}_{3} \mathrm{O}_{2}\right)\left(\mathrm{MoO}_{4}\right)_{4}$. There are $\mathrm{Bi}_{3} \mathrm{O}_{2}$ chains parallel to the $b$-axis. There are also Bi atoms bound only to $\mathrm{MoO}_{4}$ tetrahedra. Contrary to earlier reports, the isolated $\mathrm{MoO}_{4}$ tetrahedra are very regular. © 1986 Academic Press, Inc.

## Introduction

Molybdates are unsurpassed as selective oxidation catalysts for reactions such as methanol oxidation to formaldehyde and propylene ammoxidation to acrylonitrile (1). We have recently shown that ferric molybdate, a frequent component of such catalysts, contains highly regular $\mathrm{MoO}_{4}$ tetrahedra (2). Now we find the same feature in $\mathrm{Bi}_{2} \mathrm{MO}_{2} \mathrm{O}_{9}$.

Of the bismuth molybdates, the three phases showing simultaneously high activity and selectivity for the partial oxidation of hydrocarbons are $\mathrm{Bi}_{2} \mathrm{MoO}_{6}, \mathrm{Bi}_{2} \mathrm{Mo}_{2} \mathrm{O}_{9}$, and $\mathrm{Bi}_{2} \mathrm{Mo}_{3} \mathrm{O}_{12}$. The structures of $\mathrm{Bi}_{2} \mathrm{MoO}_{6}$ and $\mathrm{Bi}_{2} \mathrm{Mo}_{3} \mathrm{O}_{12}$ are known (3, 4). However, current evidence is that the best catalyst among these bismuth molybdates is $\mathrm{Bi}_{2}$ $\mathrm{Mo}_{2} \mathrm{O}_{9}$ (5), and this structure has been controversial. Good single crystals have not

[^0]been available, and a totally reliable structure has not been reported.
van der Elzen and Rieck (6) published a structure for $\mathrm{Bi}_{2} \mathrm{Mo}_{2} \mathrm{O}_{9}$ based on X-ray powder data. They approximated the monoclinic $P 2_{1} / n$ cell as an orthorhombic Pmnb cell and reported only metal positions. Although unable to locate the oxygen atoms, they suggested positions assuming distorted $\mathrm{MoO}_{4}$ tetrahedral coordination. Based on spectroscopic evidence, Haber and co-workers (7) concluded that the molybdenum coordination in $\mathrm{Bi}_{2} \mathrm{Mo}_{2} \mathrm{O}_{9}$ is mixed octahedral and tetrahedral. We have now obtained a suitable crystal of $\mathrm{Bi}_{2}$ $\mathrm{Mo}_{2} \mathrm{O}_{9}$, and an accurate structure is reported for the first time.

## Sample Preparation

The $\mathrm{Bi}_{2} \mathrm{Mo}_{2} \mathrm{O}_{9}$ sample was prepared from a mixture of $\mathrm{Bi}_{2} \mathrm{O}_{3}$ (Baker, Reagent Grade) and $\mathrm{MoO}_{3}$ (Matheson, Coleman and Bell) of mole ratio $27.5 / 72.5$. The mixture was 70
melted at $700^{\circ} \mathrm{C}$ in a $\mathrm{Pt}-\mathrm{Rh}$ crucible. A crystal pulled by the Czochralski method at $670^{\circ} \mathrm{C}$ using a $\mathrm{Pt} / 20 \%-\mathrm{Rh}$ wire rotating at 60 rmp was severely twinned. However, clear yellow fragments were isolated that showed diffraction patterns of a pseudoorthorhombic phase with $a=11.949 \AA, b=10.795 \AA$, and $c=11.877 \AA$. Several crystal fragments were examined by X-ray methods before a single crystal suitable for structure work was obtained.

## X-Ray Data Collection

A clear crystal, approximately $0.1 \times$ $0.033 \times 0.033 \mathrm{~mm}$, was mounted with the needle axis making roughly a $45^{\circ}$ angle with the spindle axis. Preliminary examination by the precession technique indicated the crystal was single and probably has orthorhombic symmetry as reported by Erman et al. (8). When examinations were carried out with a Syntex P3 diffractometer, the axial photographs with extended exposure time showed violations of mirror symmetry for two of the three orthorhombic axes. Thus, it was concluded that the structure belonged to a monoclininc rather than an orthorhombic system. With 25 reflections and their Friedel pairs, the lattice parameters at $25^{\circ} \mathrm{C}$ were refined to $a=$ 11.972(3) $\AA, b=10.813(4) \AA, c=11.899(2)$ $\AA$, and $\beta=90.13^{\circ}(2)$. From fast-scan data, the nonextinction conditions were found to be ( $h 0 l$ ): $h+l=2 n$, and ( $0 k 0$ ): $k=2 n$. This indicated space group $P 2_{1} / n$, in agreement with van der Elzen and Rieck (5).

Intensity data were collected at room temperature using the Syntex diffractometer (graphite monochromator, MoK $\alpha$ radiation, $\lambda=0.7107 \AA$ ) and the $\omega$-scan method. Because of the small crystal size, data were collected at relatively slow scan rates, 1.5 to $3 \% \mathrm{~min}$ with the X-ray tube operated at the maximum output of 2400 W . The scan range was $1^{\circ}$ with the background time equal to scan time. From $\psi$-scan data of four reflections with $2 \theta$ ranging from 8.51 to
$44.63^{\circ}$, the normalized transmission coefficients varied from 52 to $100 \%$. Accordingly, an empirical absorption correction was carried out for the intensities using the $\psi$-scan data. Totally, 5708 reflections were measured in the range of $0^{\circ}<2 \theta<50^{\circ}$ (for the hemisphere $\pm h, k, \pm l)$; after averaging, 2711 independent reflections were obtained. The output from the averaging program showed that the equivalent reflections indeed had the same intensities within the experimental error. The data were not complicated by twinning.

## Structure Determination and Refinements

Solution and refinements of the structure were accomplished on a PDP-11 computer, using local modifications of the structure determination package supplied by the Enraf-Nonius Corporation (9). The atomic scattering factors were taken from the tabulations of Cromer and Waber (10). Anomalous dispersion corrections were Cromer (10). In the full-matrix least-squares refinement, the function minimizcd was $\Sigma w\left(\left|F_{0}\right|\right.$ $\left.-\mid F_{\mathrm{d}}\right)^{2}$, where the weight, $w$, was the reciprocal of the value of $\sigma\left(F^{2}\right)+0.02 F^{2}$.
From the $E$ statistics of the data, the $\langle E\rangle$ values are all very small for $k=2 n+1$, indicating a very strong subcell character in the $b$-direction. Furthermore, the entire data depicted roughly a body-centered tetragonal cell with $a^{\circ}=a / 3, b^{\circ}=c / 3$, and $c^{\circ}=b / 2$. With the strong subcell nature, the direct method could not yield a satisfactory solution for positioning the heavy metal atoms. The Patterson map of the entire cell produced 36 distinct peaks, only 32 of which should represent the metal atoms in the actual structure. In order to locate the origin and, at the same time, exclude the four unoccupied sites, the 36 Patterson peaks were compared with the 32 atom positions proposed by van der Elzen et al. (6). It was found that if their 32 positions were to be consistent with the space group $P 2_{1} / n$, the origin should be located at $\left(\frac{3}{4}, \frac{1}{k}, \frac{1}{4}\right)$ and

Fig. 1. Structure of $\mathrm{Bi}_{2} \mathrm{Mo}_{2} \mathrm{O}_{9}$ projected in the $a-c$ plane. The unit cell is outlined with $a$ as the horizontal axis. Oxygen atoms are shaded. Molybdenum is tetrahedrally coordinated, and bismuth is eight-coordinated. The upper and lower sections are at about $z=\frac{1}{8}$ and $\frac{3}{8}$, respectively.
the $2_{1}$ screw axis at $\left(0, y, \frac{1}{2}\right)$. With this assignment of the origin, the 32 positions could be represented by the following eight independent atoms
$\mathrm{Bi}(1)$ at $\left(-\frac{1}{12}, \frac{1}{1}, \frac{3}{4}\right)$
$\mathrm{Bi}(3)$ at $\left(\frac{1}{4}, \frac{1}{8}, \frac{3}{4}\right)$
$\mathbf{M o ( 1 )}$ at $\left(-\frac{1}{12}, \frac{1}{8}, \frac{1}{12}\right)$
$\operatorname{Mo}(3)$ at $\left(\frac{7}{12}, \frac{1}{8}, \frac{1}{12}\right)$

Refinements with the 8 metal atoms led to an $R$ of 0.18 . Subsequently, 130 atoms were positioned from the difference Fourier map and refined convergently. Peaks for the remaining 5 oxygens were not found. At this stage, it was assumed that all the Mo atoms had an ideal $\mathrm{MoO}_{4}$ tetrahedral coordination and the positions of missing O atoms were calculated. Subsequent refinements quickly converged to an $R$ of 0.062 . Finally, the thermal parameters of the metal atoms were refined anisotropically, and $R=0.051$ and $R_{w}=0.057$ were obtained. The maximum residual electron density in the difference Fourier map was about $1.0 \mathrm{e}^{-} / \AA^{3}$. Conversion from iso- to anisotropic thermal parameters for O atoms did not improve the refinement, and the refinements involving the multiplicity for the metal atoms failed to show any degree of partial occupancy. It was, therefore, concluded that the correct formula was indeed $\mathrm{Bi}_{2} \mathrm{Mo}_{2} \mathrm{O}_{9}$.

The structure of $\mathrm{Bi}_{2} \mathrm{Mo}_{2} \mathrm{O}_{9}$ is shown in Figs. 1 and 2. Table I contains a summary of the crystal data; the positional and thermal parameters are given in Table II, and

Fig. 2. Structure of $\mathrm{Bi}_{2} \mathrm{Mo}_{2} \mathrm{O}_{9}$ projected in the $a-c$ plane. The unit cell is outlined with $a$ as the vertical axis. The $\mathrm{MoO}_{4}$ groups are shown as tetrahedra. The $\mathrm{Bi}_{3} \mathrm{O}_{2}$ chains along the $b$ axis are shown.

## Description of Structure

All the Mo atoms are in more or less ideal $\mathrm{MoO}_{4}$ tetrahedral configuration; the Mo-O distances are nearly equal with an average value of $1.756 \AA$, compared to $1.77 \AA$ expected from the tabulation of Shannon and Prewitt (11). The $\mathrm{O}-\mathrm{Mo}-\mathrm{O}$ angles have an average value of $109.5^{\circ}$, essentially that expected for tetrahedral coordination. The next nearest O atoms are $2.8 \AA$ away. All 4 Bi atoms are 8 -coordinated, but $\mathrm{Bi}(3)$ distinguishes itself from the others in the square antiprismatic coordination with a relatively small spread in the eight $\mathrm{Bi}-\mathrm{O}$ distances (averaged to $2.456 \AA$ ). This is similar to the $\mathrm{BiO}_{8}$ polyhedron in $\mathrm{BiVO}_{4}$ (12).

The coordinations of $\operatorname{Bi}(1), \mathrm{Bi}(2)$, and $\mathrm{Bi}(4)$ are irregular but similar to each other and typical of lone pair cations. These three Bi atoms are each bonded to two oxygens at very short distances $[O(1)$ and $O(2)]$ which are not shared with any Mo atoms. Together these bismuth and oxygen atoms form chains parallel to the $b$ axis as illustrated in Fig. 2.

As previously mentioned, the $\mathrm{Bi}_{2} \mathrm{Mo}_{2} \mathrm{O}_{9}$ structure can be viewed as an approximate body-centered arrangement of cations where $\frac{1}{9}$ of the cation positions are vacant. This leaves large cavities in the structure, which are surrounded by oxygens. Most oxygens in the $\mathrm{Bi}_{2} \mathrm{Mo}_{2} \mathrm{O}_{9}$ structure are coordinated to three cations, but some of those in the vicinity of the cavities are coordinated to only two cations.

## Discussion

The $\mathrm{Bi}_{2} \mathrm{Mo}_{2} \mathrm{O}_{9}$ structure described by van der Elzen and Rieck (6) from their powder data is remarkably close to the correct structure. They were able to locate the metal atoms and suggest approximate locations for O atoms. However, their suggestion that the $\mathrm{MoO}_{4}$ tetrahedra are strongly distorted, with the possibility of 5- to 6-coordination, is not substantiated.

Despite the similar catalytic properties of $\mathrm{Bi}_{2} \mathrm{MoO}_{6}, \mathrm{Bi}_{2} \mathrm{Mo}_{2} \mathrm{O}_{9}$, and $\mathrm{Bi}_{2} \mathrm{Mo}_{3} \mathrm{O}_{12}$, their structures are very different. The structure of $\alpha-\mathrm{Bi}_{2} \mathrm{MoO}_{6}{ }^{3}$ is composed of $\mathrm{Bi}_{2} \mathrm{O}_{2}$ layers, where bismuth shows a pronounced lonepair type bonding, and $\mathrm{MoO}_{4}$ layers with octahedra of molybdenum sharing corners. The structure of $\mathrm{Bi}_{2} \mathrm{Mo}_{3} \mathrm{O}_{12}$ is composed of isolated $\mathrm{MoO}_{4}$ tetrahedra and bismuth atoms coordinated to oxygen much as in

$\mathrm{BiVO}_{4}$. Thus, the $\mathrm{Bi}_{2} \mathrm{Mo}_{2} \mathrm{O}_{9}$ structure contains features of the $\mathrm{Bi}_{2} \mathrm{MoO}_{6}$ and $\mathrm{Bi}_{2}$ $\mathrm{Mo}_{3} \mathrm{O}_{12}$ structures. The molybdenum coordination is essentially the same as in $\mathrm{Bi}_{2} \mathrm{Mo}_{3} \mathrm{O}_{12}$ except the tetrahedra are more regular. Some bismuth in $\mathrm{Bi}_{2} \mathrm{Mo}_{2} \mathrm{O}_{9}$ is coordinated much the same as in $\mathrm{Bi}_{2} \mathrm{Mo}_{3} \mathrm{O}_{12}$, but most of the bismuth has a coordination more similar to that found in $\alpha-\mathrm{Bi}_{2} \mathrm{MoO}_{6}$. However, the strong bismuth oxygen bonding in $\alpha-\mathrm{Bi}_{2} \mathrm{MoO}_{6}$ leads to layer formation whereas in $\mathrm{Bi}_{2} \mathrm{Mo}_{2} \mathrm{O}_{9}$ this bonding leads to the formation of chains only.

## Acknowledgments

The crystals of $\mathrm{Bi}_{2} \mathrm{Mo}_{2} \mathrm{O}_{9}$ were grown by A . Ferretti. E. P. Moore and J. L. England assisted in the crystallographic work.

[^1]:    ${ }^{3} \alpha-\mathrm{Bi}_{2} \mathrm{MoO}_{6}$ refers to the low-temperature form of $\mathrm{Bi}_{2} \mathrm{MoO}_{6}$ which contains octahedral molybdenum. The high-temperature form, $\beta$ - $\mathrm{Bi}_{2} \mathrm{MoO}_{6}$, contains tetrahedral molybdenum. Regrettably, the catalyst literature frequently refers to the $\mathrm{Bi}_{2} \mathrm{MoO}_{6}$ composition as $\gamma$ bismuth molybdate.
