#### Abstract

A new sodium molybdenophosphate, $\mathrm{NaMo}_{3} \mathrm{P}_{3} \mathrm{O}_{16}$, has been isolated. It crystallizes in the triclinic system, $\mathrm{P} 1, a=6.4023$ (6) $\AA, b=7.6097(10) \AA, c=12.7395(14) \AA, \alpha=80.031(11)^{\circ}, \beta=79.039(9)^{\circ}$, $\gamma=83.517(11)^{\circ}$. The originality of this oxide, whose structure was solved from a single crystal by Xray diffraction, consists of the mixed valency of molybdenum, $\mathrm{Mo}(\mathrm{V})-\mathrm{Mo}(\mathrm{VI})$ and of the ability of molybdenum to present a trigonal bipyramidal coordination. Two independent molybdenum atoms are octahedrally coordinated and form with $\mathrm{PO}_{4}$ groups $\left[\mathrm{MoPO}_{3}\right]_{x}$ chains running along a; the third independent molybdenum atom forms $\mathrm{MoO}_{5}$ bipyramids which share two corners with $\mathrm{PO}_{4}$ tetrahedra, leading to $\left[\mathrm{MoPO}_{7}\right]_{x}$ chains running along a. The octahedral and bipyramidal sites are occupied by $\mathrm{Mo}(\mathrm{V})$ and Mo (VI), respectively, according to the formula $\mathrm{NaMo}{ }_{2}^{\frac{7}{7}} \mathrm{Mo}^{\mathrm{VI}} \mathrm{P}_{3} \mathrm{O}_{16}$. The $\left[\mathrm{Mo}_{3} \mathrm{P}_{3} \mathrm{O}_{16} \mathrm{l}_{\infty}\right.$ framework can be described by the association of these chains, connected through $\mathrm{PO}_{4}$ tetrahedra, forming five-sided tunnels where the sodium ions are located. © 1991 Academic Press, Inc.

## Introduction

The previous investigations of molybdenum phosphates have shown the great ability of the phosphate matrix to stabilize pentavalent molybdenum in an octahedral coordination forming molybdenyl cations ( $1-10$ ), contrary to pure octahedral structures for which such isolated $\operatorname{Mo}(\mathrm{V})$ species are very rarely observed. Contrary to tungsten, molybdenum does not often form mixed valent oxides, $\mathrm{Mo}(\mathrm{V})-\mathrm{Mo}(\mathrm{VI})$, if one excepts the well known molybdenum bronzes $A_{x} \mathrm{MoO}_{3}$ (1I). Another peculiarity of this element is the coexistence of several coordinations in the same matrix even for a mixed valence of molybdenum as shown for both forms of the oxide $\mathrm{Mo}_{4} \mathrm{O}_{11}$ (12), which exhibit the octahedral and tetrahedral coordinations simultaneously. No mixed va-0022-4596/91 \$3.00

lence of molybdenum involving the oxidation states V and VI has been observed up to now in molybdenophosphates. The present paper reports on the crystal structure of such a mixed valent molybdenum phosphate, $\mathrm{NaMo}_{3} \mathrm{P}_{3} \mathrm{O}_{16}$, in which molybdenum exhibits, besides the usual octahedral coordination, the rare trigonal bipyramidal coordination.

## Synthesis

Pure powder of the phosphate Na $\mathrm{Mo}_{3} \mathrm{P}_{3} \mathrm{O}_{16}$ was prepared in two steps, starting from mixture in adequate molar ratios in order to obtain the above formula. First an adequate mixture of $\mathrm{Na}_{2} \mathrm{CO}_{3}, \mathrm{H}\left(\mathrm{NH}_{4}\right)_{2} \mathrm{PO}_{4}$, and $\mathrm{MoO}_{3}$ was ground and heated up to 673 K in air to eliminate $\mathrm{CO}_{2}, \mathrm{H}_{2} \mathrm{O}$, and $\mathrm{NH}_{3}$. In the second step the appropriate quantity

of molybdenum was added and the finely ground mixture was sealed in an evacuated silica ampoulc and heated up to 973 K for 2 days.

Single crystals of this phase were prepared by a similar method, but using an ex-
cess of molybdenum oxide and heating at 1073 K instead of 973 K in the second step of synthesis. Purple single crystals for this study were indeed isolated from a mixture of nominal composition $\mathrm{NaMo}_{6} \mathrm{P}_{3} \mathrm{O}_{23}$.

The powder X-ray pattern (Table I) of

the phase was indexed in a triclinic cell in agreement with the parameters obtained from the single crystal study (Table II).

## Structure Determination

A purple crystal with dimensions 0.072 $\times 0.048 \times 0.024 \mathrm{~mm}$ was selected for the structure determination. The cell parameters reported in Table II were determined and refined by diffractometric techniques at 294 K with a least-squares refinement based upon 25 reflections with $18^{\circ}<\theta<22^{\circ}$. The data were collected on a CAD-4 Enraf-Nonius diffractometer with the data collection parameters reported in Table II. The reflections were corrected for Lorentz and polarization effects; no absorption corrections were performed.

Atomic coordinates of the molybdenum atoms were deduced from the Patterson function and the other atoms were located by subsequent Fourier series. Refinement of the atomic coordinates and their anisotropic thermal parameters led to $R=0.032$ and
$R_{w}=0.032$ and to the atomic parameters of Table III.

## Description of the Structure and Discussion

This molybdophosphate exhibits a very original $\left[\mathrm{Mo}_{3} \mathrm{P}_{3} \mathrm{O}_{16}\right]_{x}$ host lattice built up from corner sharing $\mathrm{MoO}_{6}$ octahedra, $\mathrm{MoO}_{5}$ trigonal bipyramids, and $\mathrm{PO}_{4}$ tetrahedra, forming cages where the sodium ions are located (Fig. 1).

The three independent $\mathrm{PO}_{4}$ tetrahedra, $P(1), P(2)$, and $P(3)$, share their apices with two $\mathrm{MoO}_{5}$ bipyramids + two $\mathrm{MoO}_{6}$ octahedra, four $\mathrm{MoO}_{6}$ octahedra, and one $\mathrm{MoO}_{5}$ bipyramid + three $\mathrm{MoO}_{6}$ octahedra, respec-

Note. The equivalent thermal factor $B$ is deduced from the anisotropic thermal factors $\beta_{i j}$ as $B=4 / 3\left[\beta_{11}\right.$ $a^{2}+\beta_{22} b^{2}+\beta_{33} c^{2}+\beta_{12} a b \cos \gamma+\beta_{13} a r \cos \beta+$ $\left.\beta_{23} b c \cos \alpha\right]$.

Fig. 1. Projection of $\mathrm{NaMo}_{3} \mathrm{P}_{3} \mathrm{O}_{16}$ along $\mathbf{b}$.
tively. Their geometry is usual with four nearly equal $\mathrm{P}-\mathrm{O}$ distances (Table IV).

The two independent $\mathrm{MoO}_{6}$ octahedra, $\mathrm{Mo}(1)$ and $\mathrm{Mo}(2)$, exhibit an almost regular " $\mathrm{O}_{6}$ " octahedral configuration. $\mathrm{Mo}(1)$ shares its corners with five $\mathrm{PO}_{4}$ tetrahedra, whereas $\mathrm{Mo}(2)$ is linked to four $\mathrm{PO}_{4}$ tetrahedra and one $\mathrm{MoO}_{5}$ bipyramid. Both octahedra are characterized by a free apex ( $\mathrm{O}(1)$ and $O(12)$, respectively), with a short Mo-O distance ( $1.65-1.66 \AA$ ) corresponding to this free oxygen atom, and a long distance ( $2.21-2.42 \AA$ ), the other four bonds being normal (Table IV). This geometry of $\mathrm{MoO}_{6}$ octahedra, in which molybdenum is off-centered, tending to form molybdenyl ions, is characteristic of $\operatorname{Mo}(\mathrm{V})$. The sum of the electrostatic valences calculated with the Zachariasen curves (13) confirms that both octahedral sites are occupied by pentavalent molybdenum (calculated valencies of 5.1 and 5.2 for $\mathrm{Mo}(1)$ and $\mathrm{Mo}(2)$, respectively), whereas an oxidation state close to six (5.9) is obtained for molybdenum in bipyramidal coordination, leading to the formula Na $\left(\mathrm{Mo}_{2}^{\mathrm{V}}\right)_{\text {oct }}\left(\mathrm{Mo}^{\mathrm{Vt}}\right)_{\text {bipy }} \mathrm{P}_{3} \mathrm{O}_{16}$. This phase is the eleventh $\mathrm{Mo}(\mathrm{V})$ phosphate that was isolated (1-10); it confirms the great ability of phos-
phate matrix to stabilize pentavalent molybdenum.

The bipyramidal coordination of molybdenum ( $\mathrm{Mo}(3)$ ) is quite unusual. A bipyramidal coordination has however been observed for $\mathrm{Mo}(\mathrm{VI})$ in $\mathrm{Bi}_{2}\left(\mathrm{MoO}_{4}\right)_{3}$ (14). Nevertheless, in the latter oxide, Mo is offcentered in its bipyramid so that it forms in fact a $\mathrm{MoO}_{4}$ tetrahedron. This is not the case here as shown from the interatomic Mo-O distances (Table IV). One indeed observes (Fig. 2) three normal and almost equal Mo-O distances which correspond to three oxygen atoms shared with $\mathrm{PO}_{4}$ tetrahedra (two apical oxygen $O(9)$ and $O(11)$ and one equatorial oxygen $\mathrm{O}(8)$ ), one short $\mathrm{Mo}-\mathrm{O}$ bond ( $1.66 \AA$ ) which corresponds to the free $\mathrm{O}(7)$ corner, and an intermediate Mo-O distance ( $1.70 \AA$ ) which corresponds to the $\mathrm{Mo}(3)-\mathrm{O}(10)-\mathrm{Mo}(2)$ bond.

The three-dimensional framework $\left[\mathrm{Mo}_{3}\right.$ $\left.\mathrm{P}_{3} \mathrm{O}_{16}\right]_{\infty}$ exhibits infinite $\left[\mathrm{MoPO}_{8}\right]_{\infty}$ chains of corner sharing $\mathrm{MoO}_{6}$ and $\mathrm{PO}_{4}$ polyhedra running along $\mathbf{a}$, in which one $\mathrm{MoO}_{6}$ octahedron alternates with one $\mathrm{PO}_{4}$ tetrahedron (Fig. 3a). Such a feature is characteristic of many molybdenum phosphates; it has indeed been observed for $\mathrm{MoPO}_{5}$ (1) and $\mathrm{MoAlP}_{2} \mathrm{O}_{9}$ (10).

Each of these chains shares the corners of its octahedra and tetrahedra with the tetrahedra and octahedra of another chain,

Fig. 3. (a) Infinite chains $\left[\mathrm{MoPO}_{8}\right]_{2}$ along a, (b) double chains $\left[\mathrm{Mo}_{2} \mathrm{P}_{2} \mathrm{O}_{14}\right]_{x}$ along a , (c) infinite chains $\left[\mathrm{MoPO}_{7}\right]_{x}$ along $\mathbf{a}$, (d) infinite chains $\left[\mathrm{Mo}_{2} \mathrm{PO}_{11}\right]$ along a.
respectively, forming double chains [ $\left.\mathrm{Mo}_{2} \mathrm{P}_{2} \mathrm{O}_{14}\right]_{c \infty}$ (Fig. 3b). Such double chains are generally observed in molybdenum phosphates as for instance in $\varepsilon-\mathrm{NaMo}_{2} \mathrm{P}_{3} \mathrm{O}_{13}$ (7) and $\gamma-\mathrm{CsMo}_{2} \mathrm{P}_{3} \mathrm{O}_{13}$ (6).

In a similar way, the $\mathrm{MoO}_{5}$ bipyramids and the $\mathrm{PO}_{4}$ tetrahedra form $\left[\mathrm{MoPO}_{7}\right]_{\infty}$
chains running along a (Fig. 3c) in which one $\mathrm{PO}_{4}$ tetrahedron alternates with one $\mathrm{MoO}_{5}$ bipyramid. In fact the $\left[\mathrm{MoPO}_{7}\right]_{\infty}$ chains are connected to the $\mathrm{Mo}(2)$ octahedra in such a way that each $\mathrm{MoO}_{6}$ octahedron shares one corner with one $\mathrm{MoO}_{5}$ bipyramid and one corner with one $\mathrm{PO}_{4}$ tetrahedron, forming

Fig. 4. The $\mathrm{P}(3) \mathrm{O}_{4}$ tetrahedra bonding. (a) the $\left[\mathrm{Mo}_{2} \mathrm{P}_{2} \mathrm{O}_{14}\right]_{x}$ double chains, (b) the $\left[\mathrm{MO}_{2} \mathrm{PO} \mathrm{P}_{11}\right]$ chains.

Fig. 5. Projection of $\mathrm{NaMo}_{3} \mathrm{P}_{3} \mathrm{O}_{16}$ along a showing the stacking of the chains.
$\left[\mathrm{Mo}_{2} \mathrm{PO}_{11}\right]_{\infty}$ chains (Fig. 3d). Note the $\mathrm{Mo}_{2} \mathrm{O}_{10}$ units built up from one $\mathrm{MoO}_{6}$ octahedron and one $\mathrm{MoO}_{5}$ bipyramid, which represent the only connection between Mo polyhedra in this structure.

Thus the framework $\left[\mathrm{Mo}_{3} \mathrm{P}_{3} \mathrm{O}_{16}\right]_{\infty}$ can be described as the assemblage of $\left[\mathrm{Mo}_{2} \mathrm{P}_{2} \mathrm{O}_{14}\right]_{\infty}$ double chains and $\left[\mathrm{Mo}_{2} \mathrm{PO}_{11}\right]_{\infty}$ chains, which are linked by single $\mathrm{PO}_{4}$ tetrahedra. Indeed, laterally in the (001) plane, two successive [ $\left.\mathrm{Mo}_{2} \mathrm{P}_{2} \mathrm{O}_{14}\right]_{x}$ chains are linked by $\mathrm{PO}_{4}$ tetrahedra ( $\mathrm{P}(3)$ ) (Fig. 4a), whereas two successive $\left[\mathrm{Mo}_{2} \mathrm{PO}_{11}\right]_{\infty}$ chains are also linked by the same $\mathrm{P}(3)$ tetrahedra (Fig. 4b). Along c the layers of $\left[\mathrm{Mo}_{2} \mathrm{PO}_{11}\right]_{\infty}$ and $\left[\mathrm{Mo}_{2} \mathrm{P}_{2} \mathrm{O}_{14}\right]_{\infty}$ chains are stacked in such a way that one layer of $\left[\mathrm{Mo}_{2} \mathrm{P}_{2} \mathrm{O}_{14}\right]_{\infty}$ chains alternates with a double layer of $\left[\mathrm{Mo}_{2} \mathrm{PO}_{11}\right]_{\infty}$ chains as shown from the projection onto the (100) plane (Fig. 5). The $\mathrm{P}(3)$ tetrahedra ensure the junction between these two sorts of layers forming five-sided tunnels where the sodium cations are located with $\mathrm{Na}-\mathrm{O}$ distances ranging from $2.36 \AA$ to $3.09 \AA$ (Table IV). One observes also an empty tunnel principally delimited by the free apices of the
$\mathrm{Mo}(2) \mathrm{O}_{6}$ octahedra and of the $\mathrm{Mo}(3) \mathrm{O}_{5}$ pyramids.

## Concluding Remarks

The synthesis of the molybdenum phosphate $\mathrm{NaMo}_{3} \mathrm{P}_{3} \mathrm{O}_{16}$ shows the possibility of introducing in a phosphate matrix $\mathrm{Mo}(\mathrm{V})$ and Mo(VI) simultaneously. The bond valence calculations suggest an ordered distribution of $\mathrm{Mo}(\mathrm{V})$ and $\mathrm{Mo}(\mathrm{VI})$ in the octahedral and bipyramidal sites, respectively. This feature should be studied by EPR, if one takes into consideration that one $\mathrm{MoO}_{5}$ bipyramid and one $\mathrm{MoO}_{6}$ octahedron share one corner, forming isolated $\mathrm{Mo}_{2} \mathrm{O}_{10}$ units within which electronic exchanges should be considered. This structure, and the previous ones we have studied, confirm the great flexibility of such mixed frameworks involving $\mathrm{PO}_{4}$ tetrahedra and transition metal polyhedra. The existence of $\mathrm{MoO}_{5}$ bipyramids is a very original feature of this structure, which opens the route to the synthesis of new molybdenophosphates.
