#### Abstract

A new mixed valent molybdenum monophosphate, $\mathrm{Li}_{x}$ $\mathrm{Mo}_{2} \mathrm{O}_{3}\left(\mathrm{PO}_{4}\right)_{2}$ with a tunnel structure has been synthesized. Although closely related to the monophosphate $\mathrm{Na}_{x}(\mathrm{Mo}$, $\mathrm{W})_{2} \mathrm{O}_{3}\left(\mathrm{PO}_{4}\right)_{2}$, this phase differs from the latter by its triclinic symmetry with $a=7.355(2) \AA, b=6.361(2) \AA, c=8.979(1)$ $\AA, \alpha=90.17(2)^{\circ}, \beta=106.47(2)^{\circ}, \gamma=90.26(2)^{\circ}$. The $\left[\mathrm{Mo}_{2} \mathrm{P}_{2} \mathrm{O}_{11}\right]_{\infty}$ framework is very similar to that observed for the sodium phase: it consists of $\mathrm{Mo}_{2} \mathrm{PO}_{13}$ units linked to each other through single $\mathrm{PO}_{4}$ tetrahedra forming infinite $\left[\mathrm{Mo}_{2} \mathrm{P}_{2} \mathrm{O}_{15}\right]_{\infty}$ chains running along c . The main difference with respect to the monophosphate $\mathrm{Na}_{x}(\mathrm{Mo}, \mathrm{W})_{2} \mathrm{O}_{3}\left(\mathrm{PO}_{4}\right)_{2}$ deals with the distribution of the $\mathrm{Li}^{+}$cations that are located in small tunnels with an octahedral coordination, whereas $\mathrm{Na}^{+}$ions are located in large tunnels with two kinds of coordination. This phase also differs from the molybdenotungsten monophosphate by the much lower amount of $\operatorname{Mo}(\mathrm{V})$. The distribution of the $\mathrm{Mo}(\mathrm{V})$ and $\mathrm{Mo}(\mathrm{VI})$ species over the two octahedral sites of the structure is discussed. © 1996

Academic Press, Inc.

## INTRODUCTION

Started in 1990, the research on mixed valent molybdenum phosphates has allowed five series of $\mathrm{Mo}(\mathrm{V})-\mathrm{Mo}(\mathrm{VI})$ monophosphate with an original structure in which the interpolated cation is an univalent element to be isolated (1-9). Among these numerous phosphates, only one, containing lithium, $\mathrm{LiMo}_{3} \mathrm{O}_{4}\left(\mathrm{PO}_{4}\right)_{3}(9)$, has been synthesized to date. For this reason a systematic investigation of the $\mathrm{Li}-\mathrm{Mo}-\mathrm{P}-\mathrm{O}$ system has been carried out. This investigation has also been encouraged by the recent discovery of a new monophosphate $\mathrm{Na}_{x}(\mathrm{Mo}, \mathrm{W})_{2} \mathrm{O}_{3}\left(\mathrm{PO}_{4}\right)_{2}$, with an original tunnel structure (10), but which requires the presence of a large amount of tungsten for its stabilization. We report herein on a new molybdenum monophosphate $\mathrm{Li}_{x} \mathrm{Mo}_{2} \mathrm{O}_{3}\left(\mathrm{PO}_{4}\right)_{2}$ with a $\left[\mathrm{Mo}_{2} \mathrm{P}_{2} \mathrm{O}_{11}\right]_{\infty}$ framework similar to that of the sodium phase $\mathrm{Na}_{x}(\mathrm{Mo}, \mathrm{W})_{2} \mathrm{O}_{3}\left(\mathrm{PO}_{4}\right)_{2}$, but characterized by a different $\mathrm{Mo}(\mathrm{V}) / \mathrm{Mo}(\mathrm{VI})$ ratio and especially by a different occupancy of the tunnels of the structure.

## EXPERIMENTAL

Single crystals of this new phosphate were grown from a mixture of nominal composition $\mathrm{Li}_{3} \mathrm{Mo}_{12} \mathrm{P}_{11} \mathrm{O}_{62}$. The synthesis was performed in two steps, using adequate ratios of $\mathrm{MoO}_{3}, \mathrm{Mo}, \mathrm{H}\left(\mathrm{NH}_{4}\right)_{2} \mathrm{PO}_{4}$, and $\mathrm{Li}_{2} \mathrm{CO}_{3}$ to obtain the above formulation. First, a mixture of $\mathrm{MoO}_{3}$, $\mathrm{H}\left(\mathrm{NH}_{4}\right)_{2} \mathrm{PO}_{4}$, and $\mathrm{Li}_{2} \mathrm{CO}_{3}$ was ground and heated in air to 673 K to eliminate $\mathrm{CO}_{2}, \mathrm{NH}_{3}$, and $\mathrm{H}_{2} \mathrm{O}$. In a second step, the appropriate amount of molybdenum was added and the ground mixture was sealed in an evacuated silica ampoule, then heated for 1 day at 873 K , cooled at 4.5 K per hour to 773 K and finally quenched to room temperature. In the resulting mixture, the major phase occurred as black needles with a minor phase as a brown powder which was not identified. The microprobe analysis of the black needles leads to a $\mathrm{Mo} / \mathrm{P}$ ratio (1/1) in agreement with the formula $\mathrm{Li}_{0.21} \mathrm{Mo}_{2} \mathrm{P}_{2} \mathrm{O}_{11}$ deduced from the structure determination. All the attempts to obtain pure powder failed; the X-ray patterns show only the $\mathrm{MoPO}_{5}$ phase (11).

A black needle with dimensions $0.026 \times 0.141 \times 0.026$ $\mathrm{mm}^{3}$ was selected for the structure determination. The cell parameters were determined by diffractometric techniques at 294 K with a least-squares refinement based upon 25 reflections with $18^{\circ}<\theta<22^{\circ}$. The data were collected with an Enraf-Nonius CAD4 diffractometer with the parameters reported in Table 1. The reflections were corrected for Lorentz and polarization effects and for absorption. The structure was solved with the heavy atom method. The refinements of the atomic parameters and the anisotropic thermal factors for $\mathrm{Mo}, \mathrm{P}$, and O atoms were successful in the space group $P \overline{1}$. Subsequent Fourier synthesis allowed the Li atoms to be localized. The refinement of the occupation of the Li atoms and its isotropic thermal factor led to the formulation $\mathrm{Li}_{0.21} \mathrm{Mo}_{2} \mathrm{P}_{2} \mathrm{O}_{11}$ with $R=0.037$ and $R_{\mathrm{w}}=0.034$.

## RESULTS AND DISCUSSION

Although similar to $\mathrm{Na}_{x}(\mathrm{Mo}, \mathrm{W})_{2} \mathrm{O}_{3}\left(\mathrm{PO}_{4}\right)_{2}$, the lithium phosphate $\mathrm{Li}_{x} \mathrm{Mo}_{2} \mathrm{O}_{3}\left(\mathrm{PO}_{4}\right)_{2}$ exhibits a different symmetry.

It crystallizes in the triclinic system with $a=7.355(2) \AA$, $b=6.361(2) \AA, c=8.979(1) \AA, \alpha=90.17(2)^{\circ}, \beta=$ $106.47(2)^{\circ}$, and $\gamma=90.26(2)^{\circ}$, whereas the sodium phase is monoclinic with $a=7.200(1) \AA, b=6.369(1) \AA, c=$ $9.123(1) \AA$, and $\beta=106.29^{\circ}$. The atomic coordinates (Table 2) and the projection of the structure of $\mathrm{Li}_{x} \mathrm{Mo}_{2} \mathrm{O}_{3}\left(\mathrm{PO}_{4}\right)_{2}$ on to the (010) plane (Fig. 1) show that the $\left[\mathrm{Mo}_{2} \mathrm{P}_{2} \mathrm{O}_{11}\right]_{\infty}$ framework is very similar to that previously observed for $\mathrm{Na}_{x}(\mathrm{Mo}, \mathrm{W})_{2} \mathrm{O}_{3}\left(\mathrm{PO}_{4}\right)_{2}$ [10]. It consists of molybdenum bioctahedra each sharing one apex with the same $\mathrm{PO}_{4}$ tetrahedron $\mathrm{P}(2)$, forming $\mathrm{Mo}_{2} \mathrm{PO}_{13}$ units. Along $\mathbf{c}$, the $\mathrm{Mo}_{2} \mathrm{PO}_{13}$ units are linked through single $\mathrm{P}(1)$ tetrahedra, forming infinite $\left[\mathrm{Mo}_{2} \mathrm{P}_{2} \mathrm{O}_{15}\right]_{\infty}$ chains (Fig. 2). Note that this framework can also be described as the assemblage of $\left[\mathrm{MoPO}_{8}\right]_{\infty}$ chains running along $\mathbf{b}$, in which one $\mathrm{MoO}_{6}$ octahedron alternates with one $\mathrm{PO}_{4}$ tetrahedron (Fig. 3).

The geometry of the polyhedra that form the $\left[\mathrm{Mo}_{2}\right.$ $\left.\mathrm{P}_{2} \mathrm{O}_{11}\right]_{\infty}$ framework is very similar to that observed for the $\left[\mathrm{Mo}_{1.17} \mathrm{~W}_{0.83} \mathrm{P}_{2} \mathrm{O}_{11}\right]_{\infty}$ host lattice of the sodium phosphate, as shown from the interatomic distances (Table 3). The $\mathrm{PO}_{4}$ tetrahedra are very regular with $\mathrm{P}-\mathrm{O}$ distances ranging from 1.51 to $1.55 \AA$, in agreement with the fact that each of them shares its four apices with four $\mathrm{MoO}_{6}$ octahedra. The $\mathrm{Mo}(1)$ octahedra exhibit two short $\mathrm{Mo}-\mathrm{O}$ bonds $(1.68-1.74 \AA)$, two intermediate ones $(1.97-2.00 \AA)$ and two larger ones $(2.13-2.15 \AA)$ very similar to those observed for the sodium molybdenotungstate, which is char-

Note. The Mo-O or $\mathrm{P}-\mathrm{O}$ distances are on the diagonal, above it are the $\mathrm{O} \cdots \mathrm{O}$ distances, and below it are the $\mathrm{O}-\mathrm{Mo}-\mathrm{O}$ or $\mathrm{O}-\mathrm{P}-\mathrm{O}$ angles.

Symmetry codes: (i) $x-1, y, z$; (ii) $x, y, z+1$; (iii) $1-x, y, 1-z$; (iv) $1-x, 1-y$, $1-z ;$ (v) $x, y, z-1$; (vi) $x+1, y, z$. Li-O(1), 2.153(5) $\AA ; \mathrm{Li}-\mathrm{O}(8)^{\mathrm{v}}, 2.106(4) \AA ; \mathrm{Li}-\mathrm{O}(11)^{\mathrm{v}}$, $2.252(5) \AA ; \mathrm{Li}-\mathrm{O}(1)^{\mathrm{vi}}, 2.153(5) \AA ; \mathrm{Li}-\mathrm{O}(8)^{\mathrm{vi}}, 2.106(4) \AA ; \mathrm{Li}-\mathrm{O}(11)^{\mathrm{vi}}, 2.252(5) \AA$.

FIG. 4. Octahedral coordination of the lithium.
acterized by pairs of (Mo-W)-O bonds of 1.71-1.73, 1.977-1.977, and 2.14-2.15 $\AA$, respectively. In a similar way the $\mathrm{Mo}(2)$ octahedra exhibit one shorter $\mathrm{Mo}-\mathrm{O}$ bond of $1.65 \AA$, four intermediate $\mathrm{Mo}-\mathrm{O}$ bonds ranging from 1.95 to $2.00 \AA$, and a larger one of $2.29 \AA$, to be compared to $1.69 \AA, 1.96-1.98 \AA$, and $2.21 \AA$, respectively for $\mathrm{Na}_{x}(\mathrm{Mo}$, $\mathrm{W})_{2} \mathrm{O}_{3}\left(\mathrm{PO}_{4}\right)_{2}$. It is worth pointing out that both $\mathrm{Mo}(1)$ and $\operatorname{Mo}(2)$ octahedra exhibit one free oxygen apex, which is currently observed in $\operatorname{Mo}(\mathrm{V})$ compounds. Nevertheless the geometry of the $\mathrm{Mo}(1)$ octahedra suggests that the site is fully occupied by $\operatorname{Mo}(\mathrm{VI})$ whereas $\mathrm{Mo}(\mathrm{V})$ should be localized on $\mathrm{Mo}(2)$, according to the formulation $\mathrm{Li}_{0.21}$ $\left(\mathrm{Mo}^{\mathrm{VI}}\right)_{\mathrm{M} 1}\left(\mathrm{Mo}_{0.78}^{\mathrm{VI}} \mathrm{Mo}_{0.21}^{\mathrm{V}}\right)_{\mathrm{M} 2} \mathrm{O}_{3}\left(\mathrm{PO}_{4}\right)_{2}$, in agreement with the formula previously proposed for the sodium molybdenotungstenphosphate $\mathrm{Na}_{0.75}\left(\mathrm{Mo}_{0.42}^{\mathrm{VI}} \mathrm{W}_{0.58}^{\mathrm{VI}}\right)_{\mathrm{M} 1}\left(\mathrm{Mo}_{0.75}^{\mathrm{V}} \mathrm{W}_{0.25}^{\mathrm{VI}}\right)_{\mathrm{M} 2}$ $\mathrm{O}_{3}\left(\mathrm{PO}_{4}\right)_{2}$. This distribution of the $\mathrm{Mo}(\mathrm{V})$ and $\mathrm{Mo}(\mathrm{VI})$ species is also supported by the valence calculations using the Brown and Altermatt expression (12): one indeed obtains a valence of 6.04 for $\operatorname{Mo}(1)$ and 5.64 for $\operatorname{Mo}(2)$.

The important difference between the two structures deals with the distribution of the interpolated cations in the tunnels of the structure. One indeed observes that the large tunnels are empty in the lithium molybdenophos-
phate whereas they are occupied by sodium with two kinds of coordination in the molybdenotungsten phosphate. In fact, the $\mathrm{Li}^{+}$cations are located in smaller tunnels of the structure (Fig. 1) that were empty in the sodium molybdenotungstenphosphate. In these tunnels, lithium exhibits an octahedral coordination (Fig. 4) with Li-O distances ranging from 2.106 to $2.252 \AA$.

Another difference due to the triclinic distortion is that one observes in the Li compound a little waving toward $\mathbf{b}$ of the chains running along $\mathbf{c}$, whereas in the Na compound, the centers of the polyhedra all lie in the same plane.

These results show the great ability of this $\left[\mathrm{Mo}_{2} \mathrm{P}_{2} \mathrm{O}_{11}\right]_{\infty}$ framework to accommodate cations with various coordinations and size. They suggest the possible existence of nonstoichiometric monophosphates $\mathrm{Li}_{x} \mathrm{Na}_{y} \mathrm{Mo}_{2} \mathrm{O}_{3}\left(\mathrm{PO}_{4}\right)_{2}$, characterized by a simultaneous occupation of the two kinds of tunnels by lithium and sodium, respectively. An investigation of the system $\mathrm{Li}-\mathrm{Na}-\mathrm{Mo}-\mathrm{P}-\mathrm{O}$ will be performed.
