Received May 30, 1996; accepted October 15, 1996

Colorless crystals of the new compound  $\text{Hg}_2\text{Mo}_5\text{O}_{16}$  were obtained by reaction of  $\text{HgMoO}_4$  and  $\text{MoO}_2$  in evacuated, sealed silica tubes. Their crystal structure was determined from single-crystal X-ray data:  $P2/c$ ,  $a = 913.9(1)$  pm,  $b = 551.3(1)$  pm,  $c = 1428.9(2)$  pm,  $\beta = 110.65(1)^\circ$ ,  $Z = 2$ ,  $R = 0.043$  for 2262 structure factors and 66 variable parameters. The molybdenum atoms are tetrahedrally coordinated by oxygen atoms at distances covering the range from 168.4(4) to 197.4(4) pm. Five of these tetrahedra are linked via common corners forming chains with the composition  $\text{Mo}_5\text{O}_{16}$ . The tetrahedral oxygen coordination of each molybdenum atom is augmented by two additional oxygen atoms at distances between 217.7(5) and 252.5(5) pm. The resulting distorted  $\text{MoO}_6$  octahedra are linked by common corners and edges, thus forming two-dimensionally infinite sheets, as are known for the related structure of  $\text{Cs}_2\text{Mo}_5\text{O}_{16}$ . The mercury pairs are situated between these sheets with a Hg–Hg distance of 247.4(1) pm. The structures of  $\text{Hg}_2\text{Mo}_5\text{O}_{16}$  and  $\text{Cs}_2\text{Mo}_5\text{O}_{15}$  differ in the arrangement of the metal atoms and also in the stacking of the  $\infty(\text{Mo}_5\text{O}_{16}^{2-})_n$  sheets. Distorted tetrahedral  $\text{MoO}_4$  groups, augmented by two additional, weakly bonded oxygen atoms, are found in many other molybdates. In several of these, the tetrahedra form chains via corner sharing like the five-membered  $\text{Mo}_5\text{O}_{16}$  chain in  $\text{Hg}_2\text{Mo}_5\text{O}_{16}$ . Examples are  $\text{Cs}_2\text{Mo}_7\text{O}_{22}$ ,  $\text{Cs}_2\text{Mo}_5\text{O}_{16}$ , the two modifications of  $\text{Li}_2\text{Mo}_4\text{O}_{13}$ , and  $\text{Ti}_2\text{Mo}_4\text{O}_{13}$ , where the chains are seven-, five-, and four-membered, respectively; pairs of  $\text{MoO}_4$  tetrahedra occur in  $\text{Hg}_2\text{Mo}_2\text{O}_7$ . © 1997 Academic Press

## INTRODUCTION

Only two mercury molybdates have been structurally characterized up to now. In the structure of the mercury(II) molybdate(VI)  $\text{HgMoO}_4$  the molybdenum atoms are octahedrally coordinated by oxygen atoms, and the  $\text{MoO}_6$  octahedra are linked via common edges, thus forming zig-zag chains, which are arranged parallel to each other (1). The other compound is the mercury(I) dimolybdate(VI)

$\text{Hg}_2\text{Mo}_2\text{O}_7$  (2), where the molybdenum atoms are also octahedrally coordinated by oxygen atoms. In this structure the  $\text{MoO}_6$  octahedra share edges and corners resulting in two-dimensionally infinite sheets. Similar sheets of linked  $\text{MoO}_6$  octahedra are also found in the mercury molybdate of the present publication. However, it is possible to visualize the architecture of this molybdate and several others (including that of  $\text{Hg}_2\text{Mo}_2\text{O}_7$ ) in a different way. The Mo–O distances within the  $\text{MoO}_6$  octahedra of these compounds show a large spread. If only the four shortest Mo–O distances of each  $\text{MoO}_6$  octahedron are considered, the structures can also be described by the way these distorted  $\text{MoO}_4$  tetrahedra are linked via common corners.

## SAMPLE PREPARATION AND LATTICE CONSTANTS

$\text{Hg}_2\text{Mo}_5\text{O}_{16}$  was prepared by reaction of  $\text{HgMoO}_4$  and  $\text{MoO}_2$  powders. Starting materials were  $\text{Na}_2\text{MoO}_4 \cdot 2\text{H}_2\text{O}$  (Riedel-de Haën, 99.5%),  $\text{Hg}(\text{NO}_3)_2 \cdot \text{H}_2\text{O}$  (Fluka, 99%),  $\text{MoO}_3$  (Merck, 99.5%), and molybdenum powder (Ventron, 99.9%).  $\text{HgMoO}_4$  was obtained by precipitation, reacting aqueous solutions of  $\text{Na}_2\text{MoO}_4$  and  $\text{Hg}(\text{NO}_3)_2$ .  $\text{MoO}_2$  was prepared by chemical transport of Mo and  $\text{MoO}_3$  with iodine from 1000 to 800°C (3). Well-developed crystals of  $\text{Hg}_2\text{Mo}_5\text{O}_{16}$  were obtained by annealing a mixture of  $\text{HgMoO}_4$  and  $\text{MoO}_2$  (2:1) in an evacuated, sealed silica tube for 1 week at 460°C, cooling at a rate of 100°C/h to 300°C, followed by quenching in air. The main reaction possibly proceeded by the equation  $4\text{HgMoO}_4 + 3\text{MoO}_2 \rightarrow \text{Hg}_2\text{Mo}_5\text{O}_{16} + 2\text{MoO}_3 + 2\text{Hg}$ .  $\text{Hg}_2\text{Mo}_2\text{O}_7$  (2) was observed as an additional reaction product.

The colorless, equidimensional, almost globular crystals of  $\text{Hg}_2\text{Mo}_5\text{O}_{16}$  are stable in air. Their lattice constants (Table 1) were obtained by least-squares fits of the Guinier powder data.  $\text{CuK}\alpha_1$  radiation was used with  $\alpha$ -quartz ( $a = 491.30$  pm,  $c = 540.46$  pm) as an internal standard. The identification of the diffraction lines was facilitated by intensity calculations (4) using the positional parameters of the refined structure.

<sup>a</sup>The isotropic thermal parameters  $B_{\text{eq}}$  and  $B$  are listed in units of  $10^4 \text{pm}^2$ . The anisotropic thermal parameters  $U$  ( $\text{pm}^2$ ) are defined by  $\exp[-2\pi^2(h^2a^{*2}U_{11} + \dots + 2klb^*c^*U_{23})]$ . The positional parameters were standardized using the program STRUCTURE TIDY (7). Standard deviations are listed in parentheses throughout the paper.

## STRUCTURE DETERMINATION

The intensity data for the structure determination of  $\text{Hg}_2\text{Mo}_5\text{O}_{16}$  were collected on an automated four-circle diffractometer with graphite-monochromated  $\text{MoK}\alpha$  radiation, a scintillation counter, and a pulse-height discriminator. The background was determined at both ends of each  $\theta/2\theta$  scan. Empirical absorption corrections were applied from  $\psi$ -scan data. The lattice constants obtained from the four-circle diffractometer were practically the same as those refined from the powder data. Further details of the data collection are summarized in Table 2.

The structure was solved by interpretation of the Patterson map, which led to the positions of the mercury atoms. The other atoms were located by difference Fourier

syntheses. The structure was refined by a full-matrix least-squares program using atomic scattering factors (5), corrected for anomalous dispersion (6). The weighting scheme accounted for the counting statistics. A parameter correcting for the secondary extinction was optimized during the least-squares refinements. In the final least-squares cycles the metal atoms were refined with anisotropic and the oxygen atoms with isotropic thermal parameters. A stereoplot of the structure is shown in Fig. 1. The atom parameters and interatomic distances are listed in Tables 2 and 3. The structure factor table is available from the authors (8).

<sup>a</sup> All distances shorter than 330 pm (Hg–Hg, Hg–Mo, Mo–Mo, Hg–O, Mo–O) and 240 pm (O–O) are listed.

## DISCUSSION

The mercury atoms in  $\text{Hg}_2\text{Mo}_5\text{O}_{16}$  form pairs (Fig. 2), as is known for most mercury(I) compounds. The Hg–Hg distance of 247.4(1) pm is within the range from 244.6(6) to 255.7(3) pm found for about 50 Hg–Hg bonds in some 30 mercury(I) oxocompounds, but slightly shorter than their average Hg–Hg distance of 251.3 pm (8). The short Hg–O distance of 220.8(4) pm also compares well with the average short Hg(I)–O distance of 216.6 pm observed in these 30 compounds. The corresponding Hg–Hg–O bond angle of 152.7(1)°, however, deviates considerably from the ideal value of 180°.

The molybdenum atoms have highly distorted octahedral oxygen coordination. As frequently observed for molybdates(VI) (9), the two shortest Mo–O distances of the three different molybdenum sites are in *cis* coordination (in  $\text{Hg}_2\text{Mo}_5\text{O}_{16}$  these distances vary between 168.4 and 171.6 pm), the two medium distances (which vary between 187.9 and 197.4 pm) are *trans* to each other, and the long distances (between 217.7 and 252.5 pm) have again *cis* arrangement. The averages Mo–O distances for the Mo1, Mo2, and Mo3 atoms are 200.0, 198.1, and 195.6 pm, respectively, and as could be expected (10), the largest average Mo–O distance occurs for the molybdenum atom (the Mo1 atom) that has the widest spread of Mo–O distances with the extreme values of 168.4 and 252.5 pm. The oxygen atoms occupy eight general positions. They have either two or three different metal neighbors, as can be seen from Table 3 and the lower part of Fig. 2.

If only the four shortest Mo–O distances are considered, the molybdenum coordinations may also be described as distorted tetrahedral. The corresponding  $\text{MoO}_4$  tetrahedra in  $\text{Hg}_2\text{Mo}_5\text{O}_{16}$  share corners, thus forming five-membered chains of the composition  $\text{Mo}_5\text{O}_{16}$  (Fig. 2). Therefore, all oxygen atoms of  $\text{Hg}_2\text{Mo}_5\text{O}_{16}$  are already accounted for

FIG. 2. Near-neighbor environments in the structure of  $\text{Hg}_2\text{Mo}_5\text{O}_{16}$ . Single-digit numbers correspond to the designations of the oxygen atoms. Interatomic distances are given in pm units. The thermal ellipsoids of the metal atoms correspond to the 90% probability limit; the oxygen atoms are drawn with a standardized size. In the top part of the figure the environment of the mercury pair is shown. There is a twofold axis in the viewing direction located between the mercury atoms. Strong Mo–O bonds (up to 198 pm) are indicated by solid lines. Each molybdenum atom has four strongly bonded oxygen neighbors. The corresponding  $\text{MoO}_4$  tetrahedra are linked via common corners, and thus form a five-membered chain  $\text{Mo}_5\text{O}_{16}$  with the Mo3 atom in the center on a twofold axis. Additional oxygen neighbors at greater distances augment the molybdenum coordinations to distorted octahedral. In the lower part of the figure the environments of the oxygen atoms are shown. The five molybdenum atoms of this drawing belong to three different  $\text{Mo}_5\text{O}_{16}$  chains. It can be seen that the  $\text{MoO}_6$  octahedra of adjacent chains are linked not only by common corners, but also via common edges. The bond angles around the three different kinds of common edges (interchain O1–O3 and O3–O3, intrachain O1–O5) are indicated in degrees of arc.

by considering these  $\text{MoO}_4$  tetrahedra. Similar chains of corner-shared  $\text{MoO}_4$  tetrahedra can be visualized in other molybdates; e.g., seven-, five-, and four-membered chains of the compositions  $\text{Mo}_7\text{O}_{22}$ ,  $\text{Mo}_5\text{O}_{16}$ , and  $\text{Mo}_4\text{O}_{13}$  occur in  $\text{Cs}_2\text{Mo}_7\text{O}_{22}$  (11),  $\text{Cs}_2\text{Mo}_5\text{O}_{16}$  (11), the two modifications of  $\text{Li}_2\text{Mo}_4\text{O}_{13}$  (9, 12), and in  $\text{Tl}_2\text{Mo}_4\text{O}_{13}$  (13), respectively. Corner-shared pairs  $\text{Mo}_2\text{O}_7$  have been emphasized already for  $\text{Hg}_2\text{Mo}_2\text{O}_7$  (2). As can be seen from Fig. 2 the chains in  $\text{Hg}_2\text{Mo}_5\text{O}_{16}$  are formed by the atoms  $\text{Mo1-O3-Mo2-O5-Mo3-O5-Mo2-O3-Mo1}$ . For the other just mentioned molybdates, the chains are not that readily discernible. In  $\text{Cs}_2\text{Mo}_7\text{O}_{22}$  (11) they consist of the atoms  $\text{Mo4-O11-Mo2-O4-Mo3-O2-Mo1-O2-Mo3-O4-Mo2-O11-Mo4}$ , and in  $\text{Cs}_2\text{Mo}_5\text{O}_{16}$  (11) the chain-forming atoms have the sequence  $\text{Mo3-O5-Mo2-O1-Mo1-O1-Mo2-O5-Mo3}$ . In the three compounds  $\text{Hg}_2\text{Mo}_5\text{O}_{16}$ ,  $\text{Cs}_2\text{Mo}_7\text{O}_{22}$ , and  $\text{Cs}_2\text{Mo}_5\text{O}_{16}$  the central molybdenum atoms of the chains are situated on a twofold axis, and therefore the whole chain reflects this symmetry, as can be seen for  $\text{Hg}_2\text{Mo}_5\text{O}_{16}$  in Fig. 2. In the two modifications of  $\text{Li}_2\text{Mo}_4\text{O}_{13}$  (9, 12) and in  $\text{Tl}_2\text{Mo}_4\text{O}_{13}$  (13) the chains do not contain atoms on a twofold axis. In  $\text{Tl}_2\text{Mo}_4\text{O}_{13}$  the entire chain,  $\text{Mo3-O7-Mo2-}$

$\text{O6-Mo4-O11-Mo1}$ , belongs to one asymmetric unit. This is also the case for the chains  $\text{Mo2-O10-Mo1-O16-Mo4-O4-Mo3}$  and  $\text{Mo2-O10-Mo1-O17-Mo4-O3-Mo3}$  of  $\text{L-Li}_2\text{Mo}_4\text{O}_{13}$  (9) and  $\text{H-Li}_2\text{Mo}_4\text{O}_{13}$  (12), respectively. Both compounds have additionally centrosymmetric chains with the sequence  $\text{Mo6-O13-Mo5-O1-Mo5-O13-Mo6}$  for  $\text{L-Li}_2\text{Mo}_4\text{O}_{13}$  and  $\text{Mo6-O14-Mo5-O1-Mo5-O14-Mo6}$  for  $\text{H-Li}_2\text{Mo}_4\text{O}_{13}$ . In both of these centrosymmetric chains the symmetry center is located at the O1 atoms, and in all chains the Mo-O distances are of medium length, as discussed above for the  $\text{MoO}_6$  octahedra, where the two oxygen neighbors of a molybdenum atom are in *trans* configuration.

The structure of  $\text{Hg}_2\text{Mo}_5\text{O}_{16}$  is very closely related to that of  $\text{Cs}_2\text{Mo}_5\text{O}_{16}$  (11). This is demonstrated in Fig. 3. It can be seen that the arrangement of the condensed  $\text{MoO}_6$  octahedra is practically the same for both compounds. The octahedra form two-dimensionally infinite sheets, which extend parallel to the *yz* plane. Corresponding octahedra of two adjacent sheets are at the same height of the projection direction (*y*) in  $\text{Hg}_2\text{Mo}_5\text{O}_{16}$ , while they are shifted by *b*/2 relative to each other in  $\text{Cs}_2\text{Mo}_5\text{O}_{16}$  because of the *C* centering, which doubles the *a* translation period of that compound. The chemical reason for this dissimilarity lies in the trivial difference between the mercury and the cesium atoms. The cesium atoms stay away from each other and have nine oxygen neighbors with Cs-O distances varying between 296 and 341 pm, while the mercury atoms form pairs and need only one close oxygen atom to satisfy their bonding requirements.

#### ACKNOWLEDGMENTS

We thank Dipl.-Ing. U. Rodewald and Dr. M. H. Möller for the collection of the four-circle diffractometer data and K. Wagner for the work at the scanning electron microscope. We are also indebted to Dr. G. Höfer (Heraeus Quarzschmelze) for a generous gift of silica tubes. This work was supported by the Deutsche Forschungsgemeinschaft and the Fonds der Chemischen Industrie.
