#### Abstract

A new mixed valent molybdenum monophosphate, $\mathrm{CsMo}_{6} \mathrm{O}_{10}\left(\mathrm{Mo}_{2} \mathrm{O}_{7}\right)\left(\mathrm{PO}_{4}\right)_{4}$, has been synthesized. It crystallizes in the space group $I \overline{4} 2 d$ with $a=9.953(2) \AA, c=26.413(4) \AA$. Its original three-dimensional framework $\left[\mathrm{Mo}_{8} \mathrm{P}_{4} \mathrm{O}_{33}\right]_{\infty}$ consists of corner-sharing tetraoctahedral units $\mathrm{Mo}_{4} \mathrm{O}_{20}$ with the perovskite configuration, ditetrahedral groups $\mathrm{Mo}_{2} \mathrm{O}_{7}, \mathrm{MoO}_{6}$ octahedra, and single $\mathrm{PO}_{4}$ tetrahedra. This 3D lattice forms large cages where the $\mathrm{Cs}^{+}$ions are located. An important feature of this structure deals also with the fact that the "molybdenum-oxygen" framework is itself three-dimensional. The distribution of the electrons in this structure is discussed on the basis of bond valence calculations and magnetic measurements. © 1997 Academic Press

## INTRODUCTION

Among the mixed valent $\mathrm{Mo}(\mathrm{V})-\mathrm{Mo}(\mathrm{VI})$ phosphates that have been isolated these past eight years, the cesium compounds exhibit very original frameworks with respect to other alkaline phosphates, due to the larger size of $\mathrm{Cs}^{+}$. Beside the monophosphate $\mathrm{Cs}_{3} \mathrm{Mo}_{4} \mathrm{O}_{6}\left(\mathrm{PO}_{4}\right)_{4}$ (1), isotypic of $\mathrm{K}_{2} \mathrm{Mo}_{2} \mathrm{O}_{3}\left(\mathrm{PO}_{4}\right)_{2}$ (2) which involves bioctahedral units, two cesium phosphates with an original structure were recently synthesized. The first, $\mathrm{CsMo}_{2} \mathrm{O}_{3}\left(\mathrm{PO}_{4}\right)_{2}$ (3), exhibits a layer structure involving isolated $\mathrm{MoO}_{6}$ octahedra and $\mathrm{MoO}_{5}$ bipyramids occupied by $\mathrm{Mo}(\mathrm{V})$ and $\mathrm{Mo}(\mathrm{VI})$, respectively. The second, $\mathrm{Cs}_{8+x}\left(\mathrm{MoO}_{4}\right) \mathrm{Mo}_{12} \mathrm{O}_{18}\left(\mathrm{PO}_{4}\right)_{10} \mathrm{H}_{2} \mathrm{O}(4)$, exhibits tetraoctahedral units of corner- and edge-sharing $\mathrm{MoO}_{6}$ octahedra connected through $\mathrm{MoO}_{4}$ and $\mathrm{PO}_{4}$ tetrahedra, forming an opened framework with zeolithic properties. Such results suggest that we are just at the beginning of a fascinating chemistry, and that many other original frameworks should be generated by associating the large size of cesium and the high flexibility of $\operatorname{Mo}(\mathrm{V}) / \mathrm{Mo}(\mathrm{VI})$ polyhedra in a phosphate matrix. For this reason, we have investigated $\mathrm{Cs}-\mathrm{Mo}-\mathrm{P}-\mathrm{O}$ regions corresponding to lower cesium contents. The present work deals with the structure and magnetic properties of a new mixed molybdenum monophosphate, $\mathrm{CsMo}_{6} \mathrm{O}_{10}\left(\mathrm{Mo}_{2} \mathrm{O}_{7}\right)\left(\mathrm{PO}_{4}\right)_{4}$, whose com-
plex framework is built up from tetraoctahedral $\mathrm{Mo}_{4} \mathrm{O}_{20}$ perovskite units, ditetrahedral groups $\mathrm{Mo}_{2} \mathrm{O}_{7}, \mathrm{MoO}_{6}$ octahedra, and monophosphate groups $\mathrm{PO}_{4}$ forming large cages where cesium is located

## SYNTHESIS AND CRYSTAL GROWTH

Single crystals of the title compound were grown from a nominal composition $\mathrm{CsMo}_{2} \mathrm{P}_{2} \mathrm{O}_{11}$. The growth was carried out in two steps: first, the $\mathrm{H}\left(\mathrm{NH}_{4}\right)_{2} \mathrm{PO}_{4}, \mathrm{CsNO}_{3}$, and $\mathrm{MoO}_{3}$ were mixed in an agate mortar in adequate ratios according to the composition $\mathrm{CsMo}_{1.83} \mathrm{P}_{2} \mathrm{O}_{11}$ and heated at 673 K in a platinum crucible for 2 h in air. In a second step, the resulting mixture was added to the required amount of molybdenum ( 0.17 mole ) and $5 \mathrm{wt} \%$ of CsCl . The intimately ground mixture was sealed in an evacuated silica ampoule heated in a horizontal furnace for 12 h at 953 K , then cooled at $4 \mathrm{~K} / \mathrm{h}$ down to 853 K , and finally quenched at room temperature.

From the resulting mixture two sorts of crystals were extracted: black needles that have not been identified owing to their poor quality and pink metallic plates of high quality. The latter were studied by X-ray diffraction; microprobe analysis confirmed the composition $\mathrm{CsMo}_{8} \mathrm{P}_{4} \mathrm{O}_{33}$ deduced from the structure determination.

The chemical synthesis of this phase in the form of a polycrystalline sample was performed from a sample of nominal composition $\mathrm{CsMo}_{8} \mathrm{P}_{4} \mathrm{O}_{33}$ heated at 833 K for 1 day. A pure phase was isolated and the powder X-ray pattern, registered on a PW1711/90 Philips diffractometer, was indexed in a tetragonal cell (Table 1) in agreement with parameters obtained from the single crystal study (Table 2).

## STRUCTURE DETERMINATION

A metallic pink plate-like crystal with dimensions $0.077 \times 0.052 \times 0.077 \mathrm{~mm}$ was selected for the structure determination. The cell parameters reported in Table 2 were determined and refined by diffractometric techniques at 294 K with a least squares refinement based upon 25

Enraf-Nonius diffractometer with the data collection parameters of Table 2. The reflections were corrected for Lorentz, polarization, absorption, and secondary extinction effects. The structure was solved with the heavy atom method using the XTAL package (8). A refinement of the occupation factors shows us that the $\operatorname{Mo}(3), \mathrm{O}(9)$, and Cs sites were half occupied so their occupancy factors were fixed to 0.5 in the further calculations. The refinement of the atomic coordinates and the anisotropic thermal factors was successful in the space group $I \overline{4} 2 d$ and led to $R=0.041$ and $R_{\mathrm{w}}=0.032$ for the atomic parameters of Table 3 .

## RESULTS AND DISCUSSION

## Description of the Structure

The projection of this structure along a (Fig. 1) shows the high complexity of the $\left[\mathrm{Mo}_{8} \mathrm{P}_{4} \mathrm{O}_{33}\right]_{\infty}$ framework that consists of corner-sharing $M \mathrm{O}_{6}$ octahedra, $\mathrm{PO}_{4}$ tetrahedra, and ditetrahedral groups $\mathrm{Mo}_{2} \mathrm{O}_{7}$ forming large cages where the $\mathrm{Cs}^{+}$ions are located.

The $\left[\mathrm{Mo}_{8} \mathrm{P}_{4} \mathrm{O}_{33}\right]_{\infty}$ framework can be described in a rather simple way by the stacking along $\mathbf{c}$ of two kinds of layers. The first kind of layer consists of a two-dimensional network $\left[\mathrm{Mo}_{4} \mathrm{P}_{4} \mathrm{O}_{28}\right]_{\infty}$ (Fig. 2) built up of tetraoctahedral units $\mathrm{Mo}_{4} \mathrm{O}_{20}$ characteristic of the perovskite structure interconnected through $\mathrm{PO}_{4}$ tetrahedra. The corner-sharing $\mathrm{Mo}(1)$ octahedra and $\mathrm{P}(1)$ tetrahedra that form this framework can also be described as chains along [100] and

Note. Anisotropically refined atoms are given in the form of the isotropic equivalent displacement parameter defined as $B=4 / 3 \sum_{i} \sum_{j} \mathbf{a}_{i} \cdot \mathbf{a}_{j} \beta_{i j}$.
[010], in which one $P(1)$ tetrahedron alternates with two $\mathrm{Mo}(1)$ octahedra. The second kind of layer is more difficult to describe due to a partial occupancy of several cationic and anionic sites. The basic framework of this layer which
can be formulated as $\left[\mathrm{Mo}_{4} \mathrm{O}_{2} \mathrm{O}_{21}\right]_{\infty}$ is represented in Fig. 3a. It can be described as crosslinked chains of $\mathrm{Mo}(2)$ octahedra and $\mathrm{Mo}(3)$ tetrahedra running along $\mathbf{a}$ and $\mathbf{b}$. One indeed distinguishes infinite chains of corner-sharing $\mathrm{Mo}(2)$ octahedra and $\mathrm{Mo}_{2} \mathrm{O}_{7}$ bitetrahedral $\mathrm{Mo}(3)$ running along a and chains of corner-sharing $\mathrm{Mo}(3)$ tetrahedra running along b. The $\mathrm{Mo}(2)$ sites are splitted with a classical $50 \%$ occupancy. But most important is that $50 \%$ of the tetrahedral $\mathrm{Mo}(3)$ sites are statistically unoccupied and that $50 \%$ of the $\mathrm{O}(9)$ site that corresponds to the bridging oxygen atom of the $\mathrm{Mo}_{2} \mathrm{O}_{7}$ groups is statistically occupied by cesium. Consequently, each $\left[\mathrm{Mo}_{4} \mathrm{O}_{2} \mathrm{O}_{21}\right]_{\infty}$ layer cannot be considered as two-dimensional but consists in fact of perfectly ordered " $\mathrm{Mo}_{4} \mathrm{O}_{17}$ " units built up of two $\mathrm{Mo}(2)$ octahedra interconnected by Mo (3) bitetrahedra (Fig. 3b). Between these units, the $\mathrm{Cs}^{+}$cations replace the missing " $\mathrm{Mo}_{2} \mathrm{O}$ " groups $(2 \mathrm{Mo}(3)+\mathrm{O}(9))$ in an ordered way. In two successive layers, that are spaced of $c / 4$, the " $\mathrm{Mo}_{4} \mathrm{O}_{17}$ " units are $90^{\circ}$ oriented, due to the $I \overline{4} 2 d$ symmetry. Such an ordering should involve a doubling of the $a$ parameter of the tetragonal cell. Such a phenomenon is in fact not observed, because two layers of " $\mathrm{Mo}_{4} \mathrm{O}_{17}$ " units spaced of $c / 2$ have two fixing points possible, translated $b / 2$ with respect to each other, or deduced by a simple $c / 2$ translation. The use of either fixing points is done at random. This yields a statistical $50 \%$ occupancy of the $\operatorname{Mo}(3)$ site and a statistical $50 \%$ occupancy of the $\mathrm{O}(9)$ site by $\mathrm{Cs}^{+}$.

FIG. 1. Projection of the structure of $\mathrm{CsMo}_{6} \mathrm{O}_{10}\left(\mathrm{Mo}_{2} \mathrm{O}_{7}\right)\left(\mathrm{PO}_{4}\right)_{4}$ along a.

FIG. 2. The $\left[\mathrm{Mo}_{4} \mathrm{P}_{4} \mathrm{O}_{28}\right]_{\infty}$ layer.

The " $\mathrm{Mo}_{4} \mathrm{O}_{17}$ " units are sandwiched between two $\left[\mathrm{Mo}_{4} \mathrm{P}_{4} \mathrm{O}_{28}\right]_{\infty}$ layers ensuring the cohesion of the threedimensional network. Each Mo(2) octahedron of such units shares two apices with two $\mathrm{PO}_{4}$ tetrahedra of the above layer and two other apices with two $\mathrm{PO}_{4}$ tetrahedra of the layer located below. In the same way each $\mathrm{Mo}_{2} \mathrm{O}_{7}$ group shares two apices with two $\mathrm{Mo}_{4} \mathrm{O}_{20}$ units of one layer and two other apices with one $\mathrm{Mo}_{4} \mathrm{O}_{20}$ unit of the other layer as schematized in Fig. 4.

An important characteristic of this structure deals with the fact that molybdenum polyhedra form a three-dimensional mixed framework (Fig. 5).
In this complex structure each $\mathrm{PO}_{4}$ tetrahedron shares four apices with four $\mathrm{MoO}_{6}$ octahedra $(2 \mathrm{Mo}(1)+2 \mathrm{Mo}(2))$ and is regular (Table 4), the $\mathrm{P}-\mathrm{O}$ distances ranging from 1.47 to $1.51 \AA$.

Each $\operatorname{Mo}(1)$ octahedron shares two apices with two other $\mathrm{Mo}(1)$ octahedra forming the $\mathrm{Mo}_{4} \mathrm{O}_{20}$ perovskite units, two
apices with two $\mathrm{PO}_{4}$ tetrahedra, and one apex with one $\mathrm{Mo}(3)$ tetrahedron, its sixth apex being free (i.e., not shared with an other octahedron or tetrahedron). The geometry of this octahedron suggests that it is mainly occupied by $\mathrm{Mo}(\mathrm{V})$ or at least mixed valent due to the 3D character of the molybdenum oxygen framework. One indeed observes (Table 4) one abnormally short $\mathrm{Mo}(1)-\mathrm{O}$ bond ( $1.67 \AA$ ) corresponding to the free oxygen atom, opposed to an abnormally long $\mathrm{Mo}(1)-\mathrm{O}$ bond $(2.27 \AA$ ), whereas the four equatorial $\mathrm{Mo}(1)-\mathrm{O}$ bonds exhibit intermediate values (1.86 to $2.04 \AA$ ).

In a similar way, each $\mathrm{Mo}(2)$ octahedron, which belongs to the " $\mathrm{Mo}_{4} \mathrm{O}_{17}$ " units, shares four apices of its basal plane with four $\mathrm{PO}_{4}$ tetrahedra, leading to four intermediate $\mathrm{Mo}(2)-\mathrm{O}$ bonds ranging from 1.94 to $1.95 \AA$ (Table 4). The two apical oxygen atoms $\mathrm{O}(7)$ and $\mathrm{O}\left(7^{i i}\right)$, are located at 1.78 and $2.21 \AA$, respectively. They correspond to the free apex and to the $\mathrm{Mo}(2)-\mathrm{O}(7)-\mathrm{Mo}(3)$ bond, respectively. This
configuration of the $\operatorname{Mo}(2)$ octahedron is again characteristic of pentavalent molybdenum or at least of mixed valent molybdenum $\operatorname{Mo}(\mathrm{V})-\mathrm{Mo}(\mathrm{VI})$. The fact that the distance of the free apex $\operatorname{Mo}(2)-\mathrm{O}(7)$ is slightly longer than the $\mathrm{Mo}(1)-\mathrm{O}(2)$ bond may be due to the proximity of cesium (Table 4) that forms with $\mathrm{O}(7)$ the shortest bond of the $\mathrm{CsO}_{10}$ polyhedron $(3.08 \AA$ ).

Each $\operatorname{Mo}(3)$ tetrahedron shares three apices with two $\mathrm{Mo}(1)$ octahedra and one $\mathrm{Mo}(2)$ octahedron leading to Mo-O distances of 1.84-1.90 $\AA$ and $1.81 \AA$, respectively; the fourth apex $\mathrm{O}(9)$ which corresponds to the bridging oxygen atom of the $\mathrm{Mo}_{2} \mathrm{O}_{7}$ group is located at $1.91 \AA$ (Table 4). Such $\mathrm{MoO}_{4}$ tetrahedron is typical of hexavalent molybdenum.

The interatomic $\mathrm{Cs}-\mathrm{O}$ distances, ranging from 3.08 to $3.43 \AA$ (Table 4), are those usually observed for $\mathrm{Cs}^{+}$cations.

## Electronic Distribution in the Molybdenum-Oxygen Framework

An important issue deals with the distribution of the electrons in the molybdenum oxygen framework of this phase, whose formula implies a mean valency of molybdenum of 5.62. Although they are difficult to interpret, the bond valence calculations based on a Brown and Altermatt expression (5) allow a first rough distribution to be proposed. One obtains for the octahedral sites $\mathrm{Mo}(1)$ and $\mathrm{Mo}(2)$ values of 5.52 and 5.12 , respectively. Such values indicate that $\mathrm{Mo}(\mathrm{V})$ is preferentially localized an $\mathrm{Mo}(2)$. In contrast, the $\operatorname{Mo}(1)$ site is better characterized by a mixed valence $\mathrm{Mo}(\mathrm{V})-\mathrm{Mo}(\mathrm{VI})$. Such a feature can be explained by the fact that $\mathrm{Mo}(1)$ belongs to $\mathrm{Mo}_{4} \mathrm{O}_{20}$ units, so that in the latter $d$ electrons would be delocalized over four octahedra. Calculations assuming that the $\mathrm{Mo}(3)$ site is occupied by hexavalent molybdenum lead to a resultant mean value of 5.56 for all the Mo sites of the structure in perfect agreement with the mean valence of 5.62 deduced from the chemical formula.

In order to better understand the electronic distribution over the molybdenum sites, a magnetic investigation was performed. The magnetization of $\mathrm{CsMo}_{6} \mathrm{O}_{10}\left(\mathrm{Mo}_{2} \mathrm{O}_{7}\right)$ $\left(\mathrm{PO}_{4}\right)_{4}$ was measured. The magnetic moment of a sample made of randomly oriented small pink crystals was measured with a SQUID magnetometer between 4.5 and 350 K under 1 T after zero field cooling. The sample holder signal measured in the same experimental conditions was subtracted. The resulting magnetic susceptibility is shown in Fig. 6. One can see in Fig. 6 that at $T \approx 5 \mathrm{~K}$ an antiferromagnetic transition seems to appear.

The $X(T)$ curve was fitted with the law

$$
X_{\mathrm{M}}=X_{0}+\frac{C_{\mathrm{M}}}{T-\theta}
$$

excluding the low temperature values in the antiferromagnetic ordering range. The fitting $C_{\mathrm{M}}$ parameter corresponds to $1.76 \mu_{\mathrm{B}}$. This value corresponds to one $\mathrm{Mo}(\mathrm{V})$ atom (theoretical value $1.73 \mu_{\mathrm{B}}$ ). As the formula $\mathrm{CsMo}_{8} \mathrm{P}_{4} \mathrm{O}_{33}$

FIG. 4. The connection between the $\mathrm{Mo}_{2} \mathrm{O}_{7}$ and $\mathrm{Mo}_{4} \mathrm{O}_{20}$ groups.
leads to $5 \mathrm{Mo}(\mathrm{VI})$ and $3 \mathrm{Mo}(\mathrm{V})$, the experimental value is much lower than the expected value for $3 \mathrm{Mo}(\mathrm{V})$ atoms.

Recently, a combined experimental and theoretical study of numerous molybdenum phosphates containing either only $\mathrm{Mo}(\mathrm{V})$ or mixed valent molybdenum $(\mathrm{Mo}(\mathrm{V}) / \mathrm{Mo}(\mathrm{VI})$ and $\mathrm{Mo}(\mathrm{IV}) / \mathrm{Mo}(\mathrm{V}))$ has been performed $(6,7)$. Different structural units made of one, two, three, and four $\mathrm{MoO}_{6}$ octahedra were present in the compounds investigated. A new structural classification was proposed, based on the number of octahedra in the unit built from the greater number of octahedra.

Due to the great variety of the molybdenum units concerned in this previous study $(6,7)$ different magnetic behaviors occurred. These various magnetic behaviors correspond to a large scattering of the magnetic moment per $\operatorname{Mo}(\mathrm{V})$ ranging from 0.1 to $1.73 \mu_{\mathrm{B}}$ which is the theoretical value for the spin only contribution of a $\mathrm{Mo}^{5+}$ isolated ion. These values were analyzed on the basis of qualitative arguments and confirmed by the results of numerical computations (6) using either tight binding calculations for the 3D lattices or molecular orbital calculations, calculations

FIG. 6. $X_{\mathrm{M}}$ versus $T$ curve for $\mathrm{CsMo}_{6} \mathrm{O}_{10}\left(\mathrm{Mo}_{2} \mathrm{O}_{7}\right)\left(\mathrm{PO}_{4}\right)_{4}$ showing an antiferromagnetic ordering at about $T \approx 5 \mathrm{~K}$.
restricted to the polyoctahedral molybdenum uits. The experimental values were well interpreted, the lowest moment values measured corresponding to Mo-Mo bonds and coupling of the unpaired electron of the $\mathrm{Mo}(\mathrm{V}) \mathrm{O}_{6}$ octahedra.

The monophosphate $\mathrm{CsMo}_{6} \mathrm{O}_{10}\left(\mathrm{Mo}_{2} \mathrm{O}_{7}\right)\left(\mathrm{PO}_{4}\right)_{4}$ studied here belongs to the group IV, involving tetraoctahedral units, but the situation concerning the molybdenum-oxygen polyhedral units is more complex in this compound than in the previously reported (6). In the present compound we find a new tetraoctahedral unit made of four $\mathrm{MoO}_{6}$ octahedra sharing one corner (Fig. 2). The four crystallographic $\operatorname{Mo}(1)$ sites of this unit are equivalent and, as seen above, the valence calculation using Brown and Altermatt expression leads to the 5.52 valence for $\mathrm{Mo}(1)$, i.e., two electrons for the four $\mathrm{Mo}(1)$ atoms. Moreover the $\mathrm{Mo}(1) \mathrm{O}_{6}$ octahedra show a strong $\mathrm{O}-\mathrm{Mo}-\mathrm{O}$ bond alternation and with such an octahedral distortion, two of the $t_{2 g}$ levels of the regular $\mathrm{MoO}_{6}$ octahedron are raised and only one low lying energy level $d x^{2}-y^{2}$ remains. Under these conditions, the low lying orbital of two neighbor $\mathrm{Mo}(1)$ atoms can mix with the shared oxygen atom $p$ orbital. This bonding interaction can lead to diamagnetic-like behavior and lowers the resultant magnetic moment.

Based on these qualitative arguments the experimental magnetic moment focused in $\mathrm{CsMo}_{8} \mathrm{P}_{4} \mathrm{O}_{33}$ should be mainly related to the unpaired of the $\mathrm{Mo}(2) \mathrm{O}_{6}$ octahedra in which, following Brown and Altermatt, the expression should be $\mathrm{Mo}(\mathrm{V})$. As there are two $\mathrm{Mo}(2)$ atoms for one formular unit $\mathrm{CsMo}_{8} \mathrm{P}_{4} \mathrm{O}_{33}$, the magnetic moment should be twice the experimental value if the $\mathrm{Mo}(2)$ atoms should be considered independent. The present qualitative reasons do not take account of unpaired electrons coupling through the $\mathrm{Mo}_{2} \mathrm{O}_{7}$ units. The coupling through $\mathrm{PO}_{4}$ tetrahedra has been found to be negligible in the previous study (6).

As the Mo lattice of $\mathrm{CsMo}_{8} \mathrm{P}_{4} \mathrm{O}_{33}$ is not far from being a 3D lattice, it is obvious that numerical computations in the 3D lattice are necessary to enlighten the present analysis. Such numerical computations are going to be performed to refine the present analysis.

## CONCLUDING REMARKS

A new mixed valent molybdenum monophosphate with an opened framework built up from tetraoctahedral units $\mathrm{Mo}_{4} \mathrm{O}_{20}$ with the perovskite structure and ditetrahedral $\mathrm{Mo}_{2} \mathrm{O}_{7}$ groups has been synthesized for the first time. The association of $\mathrm{MoO}_{4}$ tetrahedra and $\mathrm{MoO}_{6}$ octahedra which was previously observed in the mixed valent monophosphate $\mathrm{Cs}_{8+x}\left(\mathrm{MoO}_{4}\right) \mathrm{Mo}_{12} \mathrm{O}_{18}\left(\mathrm{PO}_{4}\right)_{10} \quad \mathrm{H}_{2} \mathrm{O}$ (4) opens the route to the investigation of new opened frameworks. The magnetic study and bond valence calculations suggest a complex electronic distribution that will be further studied by taking into consideration the fact that the "molybdenum-oxygen" mixed framework is threedimensional.
