#### Abstract

A new mixed-valent vanadium tungsten monophosphate $\mathrm{Cs}_{5} \mathrm{~V}_{2} \mathbf{W}_{4} \mathrm{O}_{13}\left(\mathrm{PO}_{4}\right)_{4}$ has been synthesized in air in spite of the presence of $\mathrm{V}(\mathrm{IV})$. It crystallizes in the space group $\mathbf{C m c} 2_{1}$ with $a=14.948(1), b=20.008(2)$, and $c=9.942(1) \AA$. Its original structure, built up from $\mathbf{W}_{2} \mathrm{O}_{11}$ bioctahedra, $\mathbf{P}_{2} \mathbf{V O}_{10}$ tritetrahedra units, and $\mathrm{VO}_{5}$ pyramids, can be described from [ $\left.\mathrm{W}_{2} \mathrm{P}_{2} \mathrm{O}_{13}\right]_{\infty}$ layers parallel to (100) interconnected through $\mathrm{VO}_{4}$ tetrahedra and $\mathrm{VO}_{5}$ pyramids. This open framework forms intersecting tunnels running along $\vec{a}$ and $\vec{c}$, where the $\mathrm{Cs}^{+}$cations are located. Bond strength-bond length calculations and magnetic measurements show that the electrons are localized, $\mathrm{V}(\mathrm{IV})$ sitting in the $\mathbf{V O}_{5}$ pyramid, whereas the $\mathbf{V O}_{4}$ tetrahedra and $\mathbf{W O}_{6}$ octahedra are occupied by $V(V)$ and $W(V I)$, respectively. © 1998

## INTRODUCTION

Transition metal phosphates have been extensively investigated over the past several years owing to the open character of their structure (for a review, see Refs. 1 and 2) and to their ability to present a mixed valence of the transition element. Thus they can be considered as potential materials for various applications such as heterogeneous catalysis, ionic conductivity, or molecular sieves.

In addition to the foregoing applications, the research of matrices for the storage of nuclear elements such as radioactive cesium calls attention to transition metal phosphates. In this respect, vanadium phosphates are of great interest, since several cesium vanadophosphates have been synthesized at temperatures ranging from 973 to $1173 \mathrm{~K}(3-8)$. Nevertheless, the synthesis of these oxides requires reducing conditions, vanadium being either trivalent (3-5) or tetravalent (5-8). Recently, a vanadium tungsten phosphate $\mathrm{Cs}_{3} \mathrm{~V}_{2} \mathrm{~W}_{2}$ $\mathrm{O}_{9}\left(\mathrm{PO}_{4}\right)_{2}$, characterized by the mixed valence $\mathrm{V}(\mathrm{V})-\mathrm{V}(\mathrm{IV})$ has been isolated (9), suggesting that mixed frameworks of the systems $\mathrm{V}-\mathrm{W}-\mathrm{P}-\mathrm{O}$ are susceptible to accommodate cesium. In the present paper, we report on a new cesium monophosphate, $\mathrm{Cs}_{5} \mathrm{VW}_{4} \mathrm{O}_{9}\left(\mathrm{VO}_{4}\right)\left(\mathrm{PO}_{4}\right)_{4}$, characterized by
a mixed valence of vanadium, $\mathrm{V}(\mathrm{IV})-\mathrm{V}(\mathrm{V})$, entirely prepared in air and at low temperature ( 783 K ).

## EXPERIMENTAL

## Crystal Growth and Chemical Synthesis

Single crystals of this phase were grown from a mixture of nominal composition $\mathrm{Cs}_{8} \mathrm{~V}_{4} \mathrm{~W}_{4} \mathrm{P}_{8} \mathrm{O}_{45}$. The growth was performed in two steps: first $\mathrm{H}\left(\mathrm{NH}_{4}\right)_{2} \mathrm{PO}_{4}, \mathrm{CsNO}_{3}$, and $\mathrm{WO}_{3}$ were mixed in adequate ratios according to the composition $\mathrm{Cs}_{8} \mathrm{~W}_{3.67} \mathrm{P}_{8} \mathrm{O}_{35}$ and heated in a platinum crucible for 2 h at 673 K to decompose the ammonium phosphate and the cesium nitrate. The required amounts of $\mathrm{V}_{2} \mathrm{O}_{5}$ $(2 \mathrm{~mol})$ and tungsten $(0.33 \mathrm{~mol})$ were then added and the resulting mixture was sealed in an evacuated silica ampoule. It was heated at 783 K for 33 h , cooled at $10 \mathrm{~K} / \mathrm{h}$ to 633 K , and finally quenched to room temperature. From the resulting product, some orange crystals were extracted. Their EDS analysis allowed the presence of silicon to be ruled out and led to the cationic composition $\mathrm{Cs}_{5} \mathrm{~V}_{2} \mathrm{~W}_{4} \mathrm{P}_{4}$, which was confirmed from the structure determination.

The synthesis of a pure powder of this new phosphate $\mathrm{Cs}_{5} \mathrm{VW}_{4} \mathrm{O}_{9}\left(\mathrm{VO}_{4}\right)\left(\mathrm{PO}_{4}\right)_{4}$ is remarkable since it can be performed entirely in air in spite of the presence of V(IV) and at low temperature $(783 \mathrm{~K})$. The synthesis was performed in two steps. In a first step $\mathrm{H}\left(\mathrm{NH}_{4}\right)_{2} \mathrm{PO}_{4}$, $\mathrm{CsNO}_{3}$, and $\mathrm{WO}_{3}$ were mixed in adequate proportions according to the ideal composition $\mathrm{Cs}_{5} \mathrm{~W}_{4} \mathrm{P}_{4} \mathrm{O}_{24.5}$ and heated in air for 2 h at 673 K . Under these conditions tungsten keeps the maximum oxidation state W(VI), and we avoid a partial reduction of vanadium due to the decomposition of ammonium phosphate, which would be difficult to control. Then in the second step, the required amounts of $\mathrm{VO}_{2}$ and $\mathrm{V}_{2} \mathrm{O}_{5}$ were added and the resulting mixture was heated in air at 783 K for 12 h and quenched to room temperature. For this temperature, vanadium keeps its initial tetravalent state.

The X-ray powder diffraction pattern of this new phase confirms its purity. It can be indexed in a monoclinic cell, in agreement with the single-crystal study (Table 1).

TABLE 1
Summary of Crystal Data, Intensity Measurements, and Structure Refinement Parameters for $\mathrm{Cs}_{5} \mathrm{VW}_{4} \mathrm{O}_{\mathbf{9}} \mathrm{VO}_{4}\left(\mathrm{PO}_{4}\right)_{4}$

| 1. Crystal data |  |
| :---: | :---: |

## Single-Crystal X-Ray Diffraction Study

Single crystals were first selected optically and then tested by the Weissenberg method. The cell parameters were determined by diffractometric techniques at 293 K with a least-squares method based upon 25 reflections in the range $18^{\circ}<\theta<22^{\circ}$.

An orange crystal with dimensions $0.114 \times 0.114 \times$ $0.064 \mathrm{~mm}^{3}$ was selected for the structure determination. The data were collected on a Enraf-Nonius CAD4 diffractometer with the parameters reported in Table 1. The reflections were corrected for Lorentz and polarization effects, for absorption, and for secondary extinction.

The Laue symmetry is mmm and the systematic extinctions $h+k=2 n+1$ for all $h k l$ and $l=2 n+1$ for $h 0 l$ are consistent with the space groups Cmcm and $\mathrm{Cmc} 2_{1}$. The Patterson function shows no Harker lines along $\vec{c}$, indicating that the space group is $C m c 2_{1}$. The structure was solved with the heavy-atom method. The refinement of the atomic coordinates and the anisotropic thermal factors of all the atoms led to $R=0.034$ and $R_{\mathrm{w}}=0.033$ and to the atomic parameters listed in Table 2.

The calculations were performed on a SparcStation with the XTAL 3.2 program.

## Magnetic Study

Magnetic susceptibility measurements were performed on a powder sample by SQUID magnetometry from 4.5 up to

300 K under 0.3 T after zero-field cooling, the magnetic field being applied after stabilization of the temperature at 4.5 K . The magnetic moment was then measured in increasing temperature up to 300 K .

## RESULTS AND DISCUSSION

The projections of the structure of this new phosphate along $\vec{c}$ (Fig. 1) and $\vec{a}$ (Fig. 2) show the great diversity of the polyhedra which form the $\left[\mathrm{V}_{2} \mathrm{~W}_{4} \mathrm{P}_{4} \mathrm{O}_{29}\right]_{\infty}$ host framework. The framework consists of corner-sharing $\mathrm{PO}_{4}$ and $\mathrm{VO}_{4}$ tetrahedra, $\mathrm{WO}_{6}$ octahedra, and $\mathrm{VO}_{5}$ pyramids. In this framework the $\mathrm{WO}_{6}$ octahedra form bioctahedral $\mathrm{W}_{2} \mathrm{O}_{11}$ units, whereas the $\mathrm{PO}_{4}$ and $\mathrm{VO}_{4}$ tetrahedra form tritetrahedral $\mathrm{VP}_{2} \mathrm{O}_{10}$ units.

The important feature which characterizes this structure deals with the fact that this tridimensional framework can be described from the stacking along $\vec{a}$ of $\left[\mathrm{W}_{2} \mathrm{P}_{2} \mathrm{O}_{13}\right]_{\infty}$ layers (Fig. 1) interconnected through $\mathrm{VO}_{4}$ tetrahedra and $\mathrm{VO}_{5}$ pyramids. In fact, the $\left[\mathrm{W}_{2} \mathrm{P}_{2} \mathrm{O}_{13}\right]_{\infty}$ layers are very similar to the $\left[\mathrm{Mo}_{2} \mathrm{P}_{2} \mathrm{O}_{13}\right]_{\infty}$ layers encountered in several molybdenum monophosphates, such as $A_{3} \mathrm{Mo}_{4} \mathrm{O}_{6}\left(\mathrm{PO}_{4}\right)_{4}$ with $A=\mathrm{Rb}$ and Tl (10), $\mathrm{Cs}_{3} \mathrm{Mo}_{4} \mathrm{O}_{6}\left(\mathrm{PO}_{4}\right)_{4}$ (11), and $A_{2} \mathrm{Mo}_{2} \mathrm{O}_{3}\left(\mathrm{PO}_{4}\right)_{2}$ with $A=\mathrm{K}, \mathrm{Rb}$, and Tl (12-14). In these layers (Fig. 3) the bioctahedral $\mathrm{W}_{2} \mathrm{O}_{11}$ units are

FIG. 1. Projection of the structure of $\mathrm{Cs}_{5} \mathrm{VW}_{4} \mathrm{O}_{9} \mathrm{VO}_{4}\left(\mathrm{PO}_{4}\right)_{4}$ along $\vec{c}$.
interconnected through $\mathrm{PO}_{4}$ groups forming eight-sided rings; within a layer each ring shares two polyhedra (one $\mathrm{PO}_{4}$ tetrahedron and one $\mathrm{WO}_{6}$ octahedron) with each of the four surrounding rings. Another interesting feature concerns the $\mathrm{VP}_{2} \mathrm{O}_{10}$ tritetrahedral units, which are also observed in $\mathrm{Ba}_{2} \mathrm{~V}_{5} \mathrm{O}_{8}\left(\mathrm{PO}_{4}\right)_{4}$ (15), where the corresponding $\mathrm{VO}_{4}$ tetrahedron also ensures the connection between two rather dense layers, but which exhibits a different composition and geometry, $\left[\mathrm{V}_{4} \mathrm{P}_{4} \mathrm{O}_{22}\right]_{\infty}$.
The interatomic distances and angles (Table 3) show that the $\mathrm{PO}_{4}$ tetrahedra, which share their apices with three $\mathrm{WO}_{6}$ octahedra and one $\mathrm{VO}_{4}$ or one $\mathrm{VO}_{5}$ pyramid, are rather regular.
The $\mathrm{WO}_{6}$ octahedra are rather strongly distorted, with $\mathrm{W}-\mathrm{O}$ distances ranging from 1.70 to 2.19 Å. The distortion
is rather different for $\mathrm{W}(1)$ and $\mathrm{W}(2)$. $\mathrm{W}(1)$ exhibits one shorter W-O bond ( $1.707 \AA$ ) corresponding to its free apex, two intermediate W-O distances ( $1.80-1.844 \AA$ ) corresponding to the apices shared with $\mathrm{V}(1)$ and $\mathrm{W}(2)$, and three longer distances ( $2.035-2.185 \AA$ ) which form the W(1)-O-P bonds. For W (2), the two shorter W-O bonds (1.72-1.73 Å) correspond to the two free apices of the octahedron, the three longer ones ( $2.00-2.16 \AA$ ) characterize the three $\mathrm{W}(2)-\mathrm{O}-\mathrm{P}$ bonds, and the intermediate distance ( $1.948 \AA$ ) corresponds to the $\mathrm{W}(1)-\mathrm{O}-\mathrm{W}(2)$ bond.
The geometry of the $\mathrm{VO}_{5}$ pyramid $(\mathrm{V}(1))$ is characteristic of the vanadyl bond behavior, with one abnormally short $\mathrm{V}-\mathrm{O}$ bond corresponding to the free apex of the pyramid, and four almost equal $\mathrm{V}-\mathrm{O}$ bonds ( $1.98-2.00 \AA$ ) corresponding to the basal plane of the pyramid.

[^0]The $\mathrm{VO}_{4}$ tetrahedron $(\mathrm{V}(2))$ exhibits two shorter $\mathrm{V}-\mathrm{O}$ distances $(1.61-1.63 \AA)$ corresponding to its two free apices and two longer ones ( $1.82 \AA$ ) which form the $\mathrm{V}-\mathrm{O}$ bonds of the $\mathrm{VP}_{2} \mathrm{O}_{10}$ tritetrahedral units.

The cesium cations are distributed over four types of sites which are all fully occupied. $\mathrm{Cs}(2)$ is located within the $\left[\mathrm{W}_{2} \mathrm{P}_{2} \mathrm{O}_{13}\right]_{\infty}$ layers, at the center of the eight-sided ring (Fig. 3), i.e., on the axis of the tunnels running along $\vec{a}$ (Fig. 2). In contrast, $\mathrm{Cs}(1), \mathrm{Cs}(3)$, and $\mathrm{Cs}(4)$ are all located between the $\left[\mathrm{W}_{2} \mathrm{P}_{2} \mathrm{O}_{13}\right]_{\infty}$ layers, at the level of the $\mathrm{VO}_{5}$ pyramid and $\mathrm{VO}_{4}$ tetrahedron (Fig. 1). $\mathrm{Cs}(3)$ sits near the axis of the tunnel running along $\vec{c}$, whereas $\mathrm{Cs}(4)$ and $\mathrm{Cs}(1)$ are located between the $\mathrm{VO}_{4}$ tetrahedra and the $\mathrm{VO}_{5}$ pyramids along $\vec{c}$, respectively. It is remarkable that, whatever the positions, one observes $\mathrm{Cs}-\mathrm{O}$ distances larger than $3 \AA$ (Table 3), which emphasizes the open character of this structure. This result is in agreement with the thermal factor values after refinement, which are rather high, ranging from 2.18 to $4.73 \AA^{2}$ Thus the coordination of cesium is difficult to define: it can be considered as ranging from seven to ten,

FIG. 3. $\mathrm{A}\left[\mathrm{W}_{2} \mathrm{P}_{2} \mathrm{O}_{13}\right]$ layer veiwed in projection along $\vec{a}$.

FIG. 4. Inverse molar magnetic susceptibility versus $T$.
if one admits that $\mathrm{Cs}-\mathrm{O}$ bonds exist for distances between cesium and oxygen smaller than $3.5 \AA$.

## Electronic Localization

From the interatomic distances, an electronic localization appears as most likely, with hexavalent tungsten sitting in octahedral sites, whereas the $\mathrm{VO}_{4}$ tetrahedra and $\mathrm{VO}_{5}$ pyramids should be occupied by pentavalent and tetravalent vanadium, respectively. The bond strength-bond length calculations (16) strongly support this hypothesis. One obtains indeed valences of $6.156,6.176,3.977$, and 4.974 for $\mathrm{W}(1), \mathrm{W}(2), \mathrm{V}(1)$, and $\mathrm{V}(2)$, respectively.
The inverse molar susceptibility $\chi_{\mathrm{m}}^{-1}(T)$ established after correction of the sample holder signal, was fit with a Curie-Weiss type law $\chi_{\mathrm{m}}=\chi_{0}+C_{\mathrm{m}} /(T-\theta)$ (Fig. 4), leading to an effective magnetic moment of $1.32 \mu_{\mathrm{B}}$ per $\mathrm{V}(\mathrm{IV})$ and to $\theta=-1.33 \mathrm{~K}$ for $\chi_{0}=-0.0001$. This value of the effective magnetic moment is significantly lower than the theoretical moment, which is $1.73 \mu_{\mathrm{B}}$ for V(IV). Since the $\mathrm{V}(\mathrm{IV}) \mathrm{O}_{5}$ pyramids share two of their apices with two $\mathrm{W}_{2} \mathrm{O}_{11}$ bioctahedral units, this difference could be attributed to the existence of the interactions between the
atoms of the $\mathrm{VW}_{4} \mathrm{O}_{25}$ pentapolyhedral units resulting from this assemblage as shown in the molybdenum phosphates (17). Molecular orbital calculations will be carried out to verify this hypothesis by studying the nature of the electronic levels in this pentapolyhedral structural unit.

## ACKNOWLEDGMENT

The authors acknowledge E. Canadel (U.A.B. Barcelona) for the molecular orbital calculations.

Note added in proof. Molecular orbital calculations have been carried out which confirm the occupancy of $\mathrm{VO}_{4}$ tetrahedra and $\mathrm{VO}_{5}$ pyramids by $\mathrm{V}^{5+}$ and $\mathrm{V}^{4+}$ respectively. They also evidence a partial delocalization of the electron of $\mathrm{V}(1)$ on $\mathrm{W}(1) \mathrm{O}_{6}$ octahedra of the $\mathrm{V}(1) \mathrm{W}(1)_{2} \mathrm{~W}(2)_{2} \mathrm{O}_{25}$ unit.
