# $\mathrm{Ba}_{8}\left(\mathrm{BN}_{2}\right)_{5} \mathrm{~F}$ : A Barium Fluoride Compound with Isolated $\mathrm{BN}_{2}^{3-}$ Units 

Franziska E. Rohrer and Reinhard Nesper<br>Inorganic Chemistry Laboratory, Eidgenössische Technische Hochschule Zürich, Universitätstrasse 6, CH-8092 Zürich, Switzerland

Received April 13, 1998; in revised form September 11, 1998; accepted September 11, 1998

#### Abstract

The compound $\mathrm{Ba}_{8}\left(\mathrm{BN}_{2}\right)_{5} \mathrm{~F}$ was synthesized from a mixture of the binary components $\mathrm{Ba}_{3} \mathrm{~N}_{2}, \mathrm{BaF}_{2}$, and BN in sealed steel ampoules at 1273 K . The structure was refined from single crystal data. $\mathrm{Ba}_{8}\left(\mathrm{BN}_{2}\right)_{5} \mathrm{~F}$ crystallizes with the triclinic symmetry $\boldsymbol{P} \overline{1}$ (No. 2) with $a=4.204(3) \AA, b=20.92(2) \AA, c=20.95(2) \AA$, $\alpha=91.74(6)^{\circ}, \quad \beta=90.03(6)^{\circ}, \gamma=93.12(7)^{\circ}, Z=4$, and $V=$ $1839(2) \AA^{3}$. The structure is built from isolated $\mathrm{BN}_{2}^{3-}$ anions, barium cations, and $\left[\mathrm{Ba}_{2} \mathrm{Ba}_{2 / 2} \mathrm{~F}\right]^{5+}$ units. (C) 1999 Academic Press

## INTRODUCTION

Since the work of Goubeau and Anselment [1] in 1961 the linear nitridoborate anion $\mathrm{BN}_{2}^{3-}$, which is isoelectronic and isostructural to $\mathrm{CO}_{2}$, has been known. Recently, we reported on four new halogenide compounds containing such anions, $M_{2} \mathrm{BN}_{2} X$, with $M=\mathrm{Ca}, \mathrm{Sr}$ and $X=\mathrm{F}, \mathrm{Cl}$ [2]. Trying to synthesize the analogous barium compounds, we did not succeed but found different structures of other compositions [3]. We report here on the compound $\mathrm{Ba}_{8}\left(\mathrm{BN}_{2}\right)_{5} \mathrm{~F}$.

## EXPERIMENTAL

The compound is synthesized from stochiometric amounts of the nitride $\mathrm{Ba}_{3} \mathrm{~N}_{2}$, the fluoride $\mathrm{BaF}_{2}$, and boron nitride. Several experiments using different compositions to obtain pure $\mathrm{Ba}_{8}\left(\mathrm{BN}_{2}\right)_{5} \mathrm{~F}$ failed. The best samples were yielded according to the following synthesis procedure. The basic educts are well mixed and heated in stainless steel ampoules to 1273 K . The temperature is kept for 10 h and then lowered to room temperature by $50 \mathrm{~K} / \mathrm{h}$. The product is a mixture of yellow needles which are intergrown and light yellow crystals of rod-like shape. The comparison of the X-ray powder patterns of the product and the calculated diagram (cf. Fig. 1) shows that the main product is $\mathrm{Ba}_{8}\left(\mathrm{BN}_{2}\right)_{5} \mathrm{~F}$ with an impurity of $\mathrm{BaF}_{2}$. The latter must be used as a flux.

We measured three different single crystals of three different syntheses. All of them showed the same lattice parameters and crystal structure. The crystal structure was
determined by single crystal X-ray diffraction. Table 1 contains the crystal data and the results of the X-ray structure determination for the single crystal of the best quality. The systematic absences belong to the space group $P \overline{1}$ or $P 1$. No higher symmetry pattern could be found. The structure was solved by direct methods and refined by the fullmatrix least-squares procedure [4]. The residual difference electron density did not give any indications of further atoms. During the anisotropic refinement B1, B2, and B4-B6 were not positively refined. A refinement in P1 lead to very large correlation matrix elements. We thus believe that $P \overline{1}$ is the correct space group, but the boron atom parameters are suffering from data errors because they are the weakest scatterers. That is why we kept the displacement parameters for the B atoms isotropic.

Atomic coordinates and displacement parameters are listed in Table 2. Bond lengths and angles are in Table 3. Structure factor tables and further information may be obtained upon request.

## CRYSTAL STRUCTURE

The crystal structure is influenced not only by the different anion types but by their varying coordination geometries, as shown in Fig. 3. The fluoride anions are surrounded by four barium cations just as in the two compounds $M_{2} \mathrm{BN}_{2} \mathrm{~F}$ with $M=\mathrm{Ca}, \mathrm{Sr}$ [2]. The tetrahedron around F 1 is quite regular, but the one around F 2 relatively irregular with $\mathrm{Ba}-\mathrm{F}$ distances of $265,2 \times 267$, and 274 pm . The large difference, about 10 pm , is a result of the size differences of the three types of ions and the different local coordinations in the structure. The edge-sharing $\mathrm{Ba}_{4} \mathrm{~F}$ tetrahedra form a one-dimensional strand along the short $a$-axis (cf. Fig. 2b).

The $M_{2} \mathrm{BN}_{2} X$ compounds $(M=\mathrm{Ca}, \mathrm{Sr} ; ~ X=\mathrm{F}, \mathrm{Cl}, \mathrm{I})$ have been described as double salts [3]. This applies for $\mathrm{Ba}_{8}\left(\mathrm{BN}_{2}\right)_{5} \mathrm{~F}$ as well. In contrast to the former compounds the low content of halogenide anions leads to vertex-sharing $\mathrm{Ba}_{4} \mathrm{~F}$ tetrahedra which are surrounded by a large number of nitridoborate anions (cf. Fig. 2). In the $M_{2} \mathrm{BN}_{2} X$ phases one-dimensional double chains of tetrahedra $(X=\mathrm{F})$,

FIG. 1. X-ray powder diagrams of $\mathrm{Ba}_{8}\left(\mathrm{BN}_{2}\right)_{5} \mathrm{~F}$ : $(\mathrm{A})$ measured powder diagram of $\mathrm{Ba}_{8}\left(\mathrm{BN}_{2}\right)_{5} \mathrm{~F}$; $(\mathrm{B})$ calculated powder diagram of $\mathrm{Ba}_{8}\left(\mathrm{BN}_{2}\right)_{5} \mathrm{~F}$; (C) measured powder diagram of $\mathrm{BaF}_{2}$.
square pyramids ( $X=\mathrm{Cl}$ ), triple chains of square pyramids and octahedra ( $M=\mathrm{Eu} ; ~ X=\mathrm{Cl}$ ), and two-dimensional monolayers of octahedra ( $M=\mathrm{Sr} ; X=\mathrm{I}$ ) have been found. In all cases the polyhedra are linked via edge-sharing. This series clearly shows that the relative sizes of cations and anions and of $M_{n} X$ polyhedra and $\mathrm{BN}_{2}^{3-}$ anions have a pronounced influence on the actual structure. In this respect, it is interesting to note that obviously there is no preferred structural solution for the hypothetical compound $\mathrm{Ba}_{2} \mathrm{BN}_{2} \mathrm{~F}$.

## DISCUSSION

## Lattice Energy Calculation

The lattice energy, Madelung factors, and point potentials were calculated using the program MADKUG [5] which utilizes an Ewald procedure (Table 4). For the calculation of all the Madelung factors the same reference
distance of $2.5 \AA$ was used. The calculation of the Madelung parts of lattice energy (MAPLE) under assumption of the formal charges shows that the energy per unit charge is fairly high compared to rocksalt.

The differences of the point potentials in the nitrogen pairs in the $\mathrm{BN}_{2}^{3-}$ units hint at a quite large polarization. All the nitrogen atoms with a higher point potential are situated towards the outside of the double layers shown in Fig. 1a, which means that a certain modulation of the lattice potential is generated not only by the different anions but also by the packing requirements.

Just as for all known nitridoborate compounds the anisotropy of the $\mathrm{BN}_{2}^{3-}$ group has a marked influence on the overall packing in $\mathrm{Ba}_{8}\left(\mathrm{BN}_{2}\right)_{5} \mathrm{~F}$. In [100] projection the $\mathrm{BN}_{2}^{3-}$ units form layers perpendicular to [010] of fairly well aligned rods with two sets of $\mathrm{Ba}^{2+}$ cations (cf. Fig. 2b). The Ba atoms of one set alternate with $\mathrm{BN}_{2}^{3-}$ groups along [001] while those of the other set are shifted to the periphery. This distribution combines with a consecutive tilting of

the rods which after five $\mathrm{BN}_{2}^{3-}$ periods generates enough space to fit in a tetrahedron which cancels the resulting curvature in the layer (cf. Fig. 2a). The unit cell contains four of such layers which are shifted against each other by approximately $\left[00 \frac{1}{2}\right]$. These mutual shifts are responsible for the low symmetry despite the fact that lattice constants are fairly close to a tetragonal situation.

## Geometry of $\mathrm{BN}_{2}^{3-}$ Anions

The cumulated double bonds in the 16e systems impose a strong linear component onto the conformation of such units. Still, packing requirements and cation-anion interactions induce distortion which may be taken to be significant. The $\mathrm{B}-\mathrm{N}$ distances in $\mathrm{Ba}_{8}\left(\mathrm{BN}_{2}\right)_{5} \mathrm{~F}$ vary only slightly
between 129 and 138 pm , which may be traced back to the different coordinations. Though, quite small compared to their standard deviations we think that these differences are significant. This is supported by the electrostatic point potentials, calculated for the nitrogen atoms. The angles vary between $169^{\circ}$ and $173^{\circ}$ and are, compared to other novel $\mathrm{BN}_{2}{ }^{3-}$ containing phases, fairly small $[2,3]$.

Comparing the local environments of the 17 barium positions four different types of coordinates exist (cf. Fig. 3). For Ba 1 to Ba 4 a neighborhood according to the formulation $\left[\mathrm{BaF}\left(\mathrm{BN}_{2}\right)_{5}\right]$ is found; the only difference occurs in the spatial distribution of the coordinated $\mathrm{BN}_{2}^{3-}$ units: Ba 5 and Ba 6 have each two fluoride neighbors and four $\mathrm{BN}_{2}^{3-}$ units $\left(\left[\mathrm{BaF}_{2}\left(\mathrm{BN}_{2}\right)_{4}\right]\right)$, while $\mathrm{Ba} 7, \mathrm{Ba} 8$, and Ba 9 have six $\mathrm{BN}_{2}^{3-}$

FIG. 2. Structure of $\mathrm{Ba}_{8}\left(\mathrm{BN}_{2}\right)_{5} \mathrm{~F}$ : barium atoms are isolated or form tetrahedra around $\mathrm{F}^{-}$anions. 1 The $\mathrm{BN}_{2}^{3-}$ units show pronounced deviations from linearity. (A) skew view along the $a$-axis of $\mathrm{Ba}_{8}\left(\mathrm{BN}_{2}\right)_{5} \mathrm{~F}$; (B) skew view along the $b$-axis of $\mathrm{Ba}_{8}\left(\mathrm{BN}_{2}\right)_{5} \mathrm{~F}$ [8].

Note. $U_{(\mathrm{eq})}$ is defined as one third of the trace of the orthogonalized $U_{i j}$ tensor. The components of the anisotropic displacement tensor take the form $-2 \pi^{2}\left[h^{2} a^{* 2} U_{11}+\cdots+2 h k a^{*} b^{*} U_{12}\right]$. All the positions are fully occupied.
ligands $\left(\left[\mathrm{Ba}\left(\mathrm{BN}_{2}\right)_{6}\right]\right)$. In all these barium surroundings (Ba1 to Ba 9 ) the $\mathrm{BN}_{2}^{3-}$ units are exclusively end-on coordinated. The local environments of the other barium atoms ( Ba 10 to Ba 17 ) show three end-on and in addition two side-on coordinated $\mathrm{BN}_{2}^{3-}$ units according to
$\left[\mathrm{Ba}\left(\mathrm{BN}_{2}\right)_{5}\right]$. In the first case chemical bonding between barium and the boron or the second nitrogen cation can be excluded; in the second interaction of barium with all three atoms of the $\mathrm{BN}_{2}^{3-}$ group is quite likely (cf. Fig. 3, Ba10).

| N15-B8-N16 | $168(1)^{\circ}$ |
| N17-B9-N18 | $171(1)^{\circ}$ |
| N19-B10-N20 | $173(2)^{\circ}$ |

The one-dimensional $\left[\mathrm{Ba}_{2} \mathrm{Ba}_{2 / 2} \mathrm{~F}\right]^{5+}$ strand not only may only be a geometrically separated moiety but can be understood as a complex polymeric cation which is surrounded by the rod-shaped nitridoborate anions and additional barium cations for charge compensation. Complex cations of related types have been found in other compound types such as the alkali metalsuboxides $\mathrm{Cs}_{11} \mathrm{O}_{3}$ [6] and Zintl phases such as $\mathrm{Ca}_{4} \mathrm{Sb}_{2} \mathrm{O}\left(\left[\mathrm{Ca}_{6} \mathrm{O}\right]^{10+}[7]\right.$, just to mention a few examples. $\mathrm{Ba}_{8}\left(\mathrm{BN}_{2}\right)_{5} \mathrm{~F}$ provides another example of the large variability which is seen in the rather new class of nitridoborate double salts.

FIG. 3. Local coordinations in $\mathrm{Ba}_{8}\left(\mathrm{BN}_{2}\right)_{5} \mathrm{~F}$ (ortep plots, $90 \%$ probability ellipsoids) [9].

TABLE 4
Results of Lattice Energy Calculation (MADKUG) for $\mathrm{Ba}_{8}\left(\mathbf{B N}_{2}\right)_{5}$ F [5]: Electrostatic Point Potentials $P$ [a.u.], First Coordination Numbers (CN), Mean Coordination Distances $\bar{d}[\mathrm{pm}]$, and Lattice Energy MAPLE [ $\mathrm{kJ} \mathrm{C}^{-2} \mathbf{~ m o l}^{-1}$ ]

| Atom | $P$ | $\mathrm{CN} / \bar{d}$ | Atom | $P$ | $\mathrm{CN} / \bar{d}$ |
