# Alkali Cation Ligating lodocuprate(I)-Based Coordination Networks with the Thiacrown Ether 1,10-Dithia-18-crown-6 

T. Röttgers and W. S. Sheldrick ${ }^{1}$<br>Lehrstuhl für Analytische Chemie, Ruhr-Universität Bochum, D-44780 Bochum, Germany

The lamellar coordination polymer ${ }_{\infty}^{2}$ [CuI(1,10DT18C6)] (1) $(1,10 \mathrm{DT} 18 \mathrm{C} 6=1,10$-dithia-18-crown-6) may be prepared by reaction of CuI with the thiacrown ether in acetonitrile. 1 crystallizes in the monoclinic space group $P 2_{1} / n$ with $a=10.764(2)$, $b=14.317(3), \quad$ and $\quad c=12.335(3) \AA, \quad \beta=98.08(3)^{\circ}$, $V=1882.0(7) \AA^{3}, Z=4, R=0.041, w R_{2}=0.102$ for 5480 reflections and contains $(\mathbf{C u I})_{2}$ rhomboid dimers as characteristic building units. Performing the reaction in the presence of an equimolar quantity of alkali metal halide $M I\left(M^{+}=\mathrm{Na}^{+}, \mathrm{K}^{+}\right)$in acetonitrile solution at $100^{\circ} \mathrm{C}$ leads to formation of ion-ligating iodocuprate( I )-based two-dimensional coordination networks in ${ }_{\infty}^{2}\left[\left\{\mathrm{Na}\left(\mathrm{CH}_{3} \mathrm{CN}\right)\right\}\left\{\mathrm{Cu}_{5} \mathrm{I}_{6}(\mathbf{1}, 10 \mathrm{DT} 18 \mathrm{C} 6)\right\}\right] \quad$ (2) and $\left.{ }_{\infty}^{2}\left[\mathrm{~K}_{\{ } \mathrm{Cu}_{4} \mathrm{I}_{5}(1,10 \mathrm{DT18C6})_{2}\right\}\right]$ (3). Both anionic frameworks contain characteristic iodocuprate $(\mathrm{I})$ chains that are bridged in a $\mu$-S1,S10 manner by 1,10DT18C6 macrocycles. However, the structure-directing influence of the alkali metal cation manifests itself in both the connectivity pattern and the stoichiometry of the resulting CuI-based network. 2 is chiral and crystallizes in the monoclinic space group $P 2_{1}$ with $a=10.456(4), b=13.674(6)$, and $c=11.535(5) \AA, \beta=92.82(3)^{\circ}, V=1647.3(12) \AA^{3}, Z=2$, $R=0.049, w R_{2}=0.110$ for 3018 reflections. 3 is likewise monoclinic, space group $P 2 / n$ with $a=11.418(6), b=12.521(7)$, and $c=15.398(7) \AA, \quad \beta=96.58(3)^{\circ}, \quad V=2187(2) \AA^{3}, \quad Z=2$, $R=0.064, w R_{2}=0.176$ for 3858 reflections. After losing their coordinated acetonitrile molecules at $180^{\circ} \mathrm{C}$, the lamellar coordination networks of 2 retain their integrity up to $230^{\circ} \mathrm{C}$ before loss of their bridging thiacrown ethers. © 2000 Academic Press

Key Words: iodocuprates (I); 1,10-dithia-18-crown-6; coordination polymers; lamellar networks; crystal engineering.

## INTRODUCTION

The construction of porous solid-state coordination networks capable of reversibly hosting selected guest molecules or ions in their voids is a topic of considerable current interest (1-4). Although a number of known examples do contain $4,4^{\prime}$-bipyridine ( $5-11$ ), attempts to design two- or three-dimensional frameworks with larger channels have

[^0]often been foiled when employing rigid organic spacer molecules by the self-interpenetration of multiple networks, so as to eliminate the void space (12). Rational crystal engineering strategies to enable a systematic modification of cavity size and chemical environment must, therefore, also prevent lattice interweaving, while retaining a given supramolecular architecture.

In the past, rigid bi- and tridentate N -donor ligands such as pyrazine or $4,4^{\prime}$-bipyridine have often been chosen as molecular building blocks for the design of network topologies. However, a few encouraging reports on the employment of more flexible connecting ligands such as methylenebridged dichalcogenoethers (13), thioether macrocycles (14-16), or functionalized pendant-arm derivatives of 1,4,7triazacyclononane (17) have appeared in the recent literature. In analogy to the porous networks of zeolites, the resulting layers or frameworks might be expected to be capable of undergoing elastic deformations in response to structure-directing agents or imbibed molecular guests.

The characteristic ability of alkylcycloarsoxanes $(\mathrm{RAsO})_{n}$ ( $n=4,5 ; R=\mathrm{CH}_{3}, \mathrm{C}_{2} \mathrm{H}_{5}$ ) to bridge tetrahedrally coordinated metal atoms, taken together with their pronounced conformative flexibility and their confirmed selective ligating properties for alkali cations (18), suggested to us that such macrocyclic ligands would exhibit considerable potential as spacer molecules for the construction of functional porous networks. These considerations led us prepare a series of one- to three-dimensional polymers (19-21), in which copper(I) halides were employed to render tailored complementary building blocks such as $(\mathrm{CuX})_{2}$ rhomboid dimers or ${ }_{\infty}^{1}[\mathrm{Cu} X]$ single and double chains under selfassembly conditions (22). Both neutral and anionic coordination networks can be generated in this manner. For instance, discrete $\left[\mathrm{Cu}_{6} \mathrm{I}_{8}\right]^{2-}$ units are linked by tetrameric cyclo- $\left(\mathrm{CH}_{3} \mathrm{AsO}\right)_{4}$ into infinite anionic chains that coordinate the $\mathrm{Cs}^{+}$counterions in a $\kappa^{8} O$ manner in the layered structure of $\left[\mathrm{Cs}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]\left(\mathrm{Cu}_{3} \mathrm{I}_{4}\left\{\text { cyclo }-\left(\mathrm{CH}_{3} \mathrm{AsO}\right)_{4}\right\}_{2}\right]$ (23). We have now extended this design strategy to the crown ether 1,10-dithia-18-crown-6 (1,10DT18C6) (24) and report the preparation, structure, and properties of the two-
dimensional coordination polymers ${ }_{\infty}^{2}[\mathrm{CuI}(1,10 \mathrm{DT} 18 \mathrm{C} 6)]$ (1), $\quad{ }_{\infty}^{2}\left[\left\{\mathrm{Na}\left(\mathrm{CH}_{3} \mathrm{CN}\right)\right\}\left\{\mathrm{Cu}_{5} \mathrm{I}_{6}(1,10 \mathrm{DT} 18 \mathrm{C} 6)\right\}\right] \quad$ (2), and ${ }_{\infty}^{2}\left[\mathrm{~K}_{\left.\left\{\mathrm{Cu}_{4} \mathrm{I}_{5}(1,10 \mathrm{DT} 18 \mathrm{C} 6)_{2}\right\}\right] \text { (3). }}^{\text {(3) }}\right.$

## EXPERIMENTAL SECTION

1,10-Dithia-18-crown-6 (1,10DT18C6) was prepared according to the literature procedure (24). Elementary analyses for C,H,N were performed on a Vario El (Elementar Analysen-systeme GmbH ), the thermogravimetric analysis (TGA/DTA) on an Exstar 6000 (Seiko Instruments), and the powder X-ray diffraction study on a Bruker AXS D8 Advance.

## Syntheses

${ }_{\infty}^{2}[\operatorname{CuI}(1,10 D T 18 C 6)]$ (1). In acetonitrile solution, 38.1 mg of $\mathrm{CuI}(0.2 \mathrm{mmol})$ and $59.2 \mathrm{mg}(0.2 \mathrm{mmol})$ of 1,10DT18C6 (1,10-dithia-18-crown-6) were refluxed for 3 h . Leaving the solution to stand at room temperature over a period of 2 d led to growth of colorless crystals of $\mathbf{1}$ in $79 \%$ yield $(77 \mathrm{mg})$. Elemental analysis, $\mathrm{C}_{12} \mathrm{H}_{24} \mathrm{CuIO}_{4} \mathrm{~S}_{2}$, $M=486.87$; C 29.3 (calc 29.6), H 4.9 (calc 4.9), S 13.4 (calc 13.2) \%.
${ }_{\infty}^{2}\left[\left\{\mathrm{Na}\left(\mathrm{CH}_{3} \mathrm{CN}\right)\right\}\left\{\mathrm{Cu}_{5} \mathrm{I}_{6}(1,10 \mathrm{DT} 18 \mathrm{C} 6\}\right)\right]$ (2). In 2 ml of $\mathrm{CH}_{3} \mathrm{CN}, 38.1 \mathrm{mg}$ of $\mathrm{CuI}(0.2 \mathrm{mmol}), 59.2 \mathrm{mg}$ of $1,10 \mathrm{DT} 18 \mathrm{C} 6$ $(0.2 \mathrm{mmol})$, and 30.0 mg of $\mathrm{NaI}(0.2 \mathrm{mmol})$ were dissolved and heated in a sealed glass tube ( $\sim 10 \mathrm{ml}$ capacity) at $100^{\circ} \mathrm{C}$ for 40 h . Slow cooling to room temperature at $1^{\circ} \mathrm{C} \cdot \mathrm{h}^{-1}$ afforded colorless crystals of 2 in $78 \%$ yield $(45 \mathrm{mg})$ based on Cu . Elemental analysis, $\mathrm{C}_{14} \mathrm{H}_{27} \mathrm{Cu}_{5} \mathrm{I}_{6} \mathrm{NNaO}_{4} \mathrm{~S}_{2}$, $M=1439.58:$ C 11.5 (calc 11.7), H 1.9 (calc 1.9), N 0.9 (calc 1.0), S 4.4 (calc 4.5) \%.
${ }_{\infty}^{2}\left[K\left\{C u_{4} I_{5}(1,10 D T 18 C 6)_{2}\right\}\right]$ (3). In 2 ml of acetonitrile solution, 38.1 mg of $\mathrm{CuI}(0.2 \mathrm{mmol}), 59.2 \mathrm{mg}$ of $1,10 \mathrm{DT18C6}$ ( 0.2 mmol ), and 33.2 mg of KI ( 0.2 mmol ) were heated at $100^{\circ} \mathrm{C}$ for 40 h in a sealed glass tube. Slow cooling to room temperature at $1{ }^{\circ} \mathrm{C} \cdot \mathrm{h}^{-1}$ led to growth of colorless crystals of $\mathbf{3}$ in $83 \%$ yield ( 63 mg ) based on Cu . Elemental analysis, $\mathrm{C}_{24} \mathrm{H}_{48} \mathrm{Cu}_{4} \mathrm{I}_{5} \mathrm{KO}_{4} \mathrm{~S}_{2}, \quad M=1520.62$ : C 19.21 (calc 19.0), H 3.1 (calc 3.2), S 8.57 (calc 8.4)\%.

## X-Ray Structural Analyses

Crystal and refinement data are listed for $\mathbf{1 - 3}$ in Table 1. Unit cell constants were obtained from least-squares fits to the settings of 25 reflections $\left(20^{\circ} \leq 2 \theta \leq 30^{\circ}\right)$ centered on a Siemens P4 diffractometer. Intensity data were collected on this instrument in the $\omega$ mode at 293 K . Three selected reflections, that were monitored at regular intervals during the course of data collection for each of the compounds, exhibited no significant deviations in intensity. Absorption corrections were performed for $\mathbf{1}$ and $\mathbf{3}$ on the basis of

$\psi$ scan data (nine chosen reflections with high $\chi$ values) and for 2 using DIFABS (25). After structure solution with SHELXS-86 (26), positional parameters and anisotropic temperature factors were refined against $F_{0}^{2}$ with SHELXL93 (27). C5-C9 of one of the 1,10DT18C6 ligands in $\mathbf{3}$ are disordered with partial occupation factors of 0.667 and 0.333 . Hydrogen atoms were included at calculated positions for nondisordered carbon atoms with their isotropic temperature factors coupled to those of the parent carbon atoms. Atom coordinates and equivalent isotropic temperature factors are listed for 1-3 in Table 2, selected bond lengths and angles in Tables 3-5. Crystallographic data for these compounds have been deposited with the Cambridge Crystallographic Data Centre (CCDC 135283-135285). Copies may be obtained free of charge on application to the Director, CCDC, 12 Union Road, Cambridge CB2 1 E2, UK (fax int. code $+44(0)$ 1223/336-033, e-mail deposit@ chemcrys.cam.ac.uk).

## RESULTS AND DISCUSSION

The lamellar coordination polymer ${ }_{\infty}^{2}[\mathrm{CuI}(1,10 \mathrm{DT} 18 \mathrm{C} 6)]$ (1) crystallizes from an equimolar $\mathrm{CuI} / 1,10 \mathrm{DT} 18 \mathrm{C} 6$

reaction mixture in acetonitrile solution and contains $(\mathrm{CuI})_{2}$ rings as characteristic building blocks (Fig. 1). These are linked by 1,10DT18C6 macrocycles in a $\mu-S 1$, S10 fashion to construct corrugated sheets, whose connectivity pattern is depicted in Fig. 2. On regarding the $(\mathrm{CuI})_{2}$ lozenges as junctions in the lamellar network, it is possible to recognize a simple $4^{4}$ net similar to that previously observed in ${ }_{\infty}^{2}\left[\mathrm{Cu}_{2} X_{2}\left\{\text { cyclo- }\left(\mathrm{CH}_{3} \mathrm{AsO}\right)_{4}\right\}_{2}\right] \quad(X=\mathrm{Cl}, \mathrm{Br}(20))$. As illustrated in Fig. 3, individual thiacrown ligands of the large 48 -membered $\left[\mathrm{Cu}_{6} \mathrm{I}_{4}(1,10 \mathrm{DT} 18 \mathrm{C} 6)_{4}\right]$ rings of $\mathbf{1}$ are alternatingly orientated on opposite sides of the polymeric

oligomeric and polymeric $\mathrm{Cu} X$ substructures have been found in copper(I) halide-based coordination polymers of rigid N -donor ligands, for instance both cubane-like and tricyclic $\mathrm{Cu}_{4} X_{4}$ tetramers, zigzag helical ${ }_{\infty}^{2}[\mathrm{Cu} X]$ single chains, and staircase or spirocyclic ${ }_{\infty}^{2}[\mathrm{Cu} X]$ double chains $(28,29)$. The formation of infinite chains in $\mathbf{1}$ is apparently prevented by both the size and conformational flexibility of the participating 1,10DT18C6 thiacrown ligands, which successfully adjust to fill the potential voids of the resulting $4^{4}$ net. Inspection of Figs. 2 and 3 suggests that 1 could be capable of selectively imbibing alkali metal salts between its sheets by coordinating their hard monovalent cations $M^{+}$through its 1,10DT18C6 O-donor atoms. The alternative approach toward the design of ion ligating networks presented in this work involves performing the self-assembly reaction between $\mathrm{Cu} X$ and the thiacrown ether in the presence of $M X$. As illustrated in a schematic fashion for theor-

FIG. 1. Numbering scheme in the asymmetric unit of ${ }_{\infty}^{2}[\mathrm{CuI}(1,10 \mathrm{DT} 18 \mathrm{C} 6)]$ (1).

FIG. 2. Two-dimensional network of 1.
etical examples in Fig. 4, two general types of anionic coordination polymers could potentially result from such a process: (a) infinite chains ${ }_{\infty}^{1}\left[\mathrm{Cu}_{\mathrm{a}} X_{\mathrm{b}}(1,10 \mathrm{DT} 18 \mathrm{C} 6)_{\mathrm{c}}\right]$ with intrastrand bridging or (b) lamellar frameworks ${ }_{\infty}^{2}\left[\mathrm{Cu}_{\mathrm{a}} X_{\mathrm{b}}(1,10 \mathrm{DT} 18 \mathrm{C} 6)_{\mathrm{c}}\right]$ with interstrand bridging. A version of the former type (Fig. 4a) has previously been found in $\left[\mathrm{Cs}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]\left[\left(\mathrm{Cu}_{3} \mathrm{I}_{4}\left\{\text { cyclo- }\left(\mathrm{CH}_{3} \mathrm{AsO}\right)_{4}\right\}_{2}\right]\right.$, in which discrete $\left[\mathrm{Cu}_{6} \mathrm{I}_{8}\right]^{2-}$ units are linked by bridging methylcycloarsoxane tetramers into infinite chains (23). Both the stoichiometry and connectivity pattern of any resulting coordination polymer will, of course, be expected to intimately
depend on the size and desired coordination number of the structure-directing alkali cation $M^{+}$, a state of affairs that is clearly reflected in the structures of $\mathbf{2}$ and $\mathbf{3}$. A sheetlike network with interstrand bridging of the general type shown in Fig. 4b is found for both coordination polymers, However, although identical equimolar ratios of $\mathrm{Cu} X / M X /$ 1,10DT18C6 were employed in both cases, strikingly different stoichiometries are apparent for ${ }_{\infty}^{2}\left[\left\{\mathrm{Na}\left(\mathrm{CH}_{3} \mathrm{CN}\right)\right\}\right.$ $\left.\left\{\mathrm{Cu}_{5} \mathrm{I}_{6}(1,10 \mathrm{DT} 18 \mathrm{C} 6)\right\}\right]$ (2) and ${ }_{\infty}^{2}\left[\mathrm{~K}\left\{\mathrm{Cu}_{4} \mathrm{I}_{5}(1,10 \mathrm{DT18C} 6)_{2}\right\}\right]$ (3). The asymmetric unit of the former complex is depicted in Fig. 5, which highlights the coordination of the $\mathrm{Na}^{+}$ions

FIG. 4. Two possible types of halocuprate(I)-based networks with ion ligating 1,10DT18C6 thiacrown ethers: (a) single chains with $1,3: 2^{\prime}, 4^{\prime}$ intrastrand bridging, (b) sheets with $1: 2^{\prime}$ interstrand bridging. Numbers refer to the position of copper atoms in the sequence of the ${ }_{\infty}^{1}[\mathrm{Cu} X]$ staircase and dashes to the opposite side of the backbone. Additional halogen atoms, that would be required to provide the halocuprate(I) chains with a negative charge, have been omitted.
through four O and one S atom of a single 1,10DT18C6 macrocycle. The sixth position trans to S 1 in a distorted octahedron is occupied by the N atom of a guest acetonitrile molecule. S1 and S10 of the thiacrown ether coordinate respectively Cu 2 und Cu 4 of adjacent iodocuprate(I) pillars ${ }_{\infty}^{1}\left[\left\{\mathrm{Cu}_{5} \mathrm{I}_{6}\right\}^{-}\right]$which contain a helical ${ }_{\infty}^{1}[\mathrm{CuI}]$ double chain as their structural backbone. Completion of the distorted
tetrahedral coordination spheres of Cu 1 and Cu 3 is achieved through the presence of an additional bridging iodine atom I6, that of Cu 5 by I2 of the double chain.

Figure 6 illustrates the connectivity pattern within the chiral two-dimensional framework of 2, whose absolute structure was established on the basis of its Flack parameter (30) of $-0.03(7)$. Propagation of the asymmetric unit by the

FIG. 5. Asymmetric unit and numbering scheme of ${ }_{\infty}^{2}\left[\left\{\mathrm{Na}\left(\mathrm{CH}_{3} \mathrm{CN}\right)\right\}\left\{\mathrm{Cu}_{5} \mathrm{I}_{6}(1,10 \mathrm{DT} 18 \mathrm{C} 6)\right\}\right]$ (2). Selected bond lengths ( $\AA$ ) and angles ( ${ }^{\circ}$ ) in the octahedral $\mathrm{Na}^{+}$coordination sphere: $\mathrm{Na} 1-\mathrm{S} 1$ 3.11(1), Na1-O4 2.51(2), Na1-O7 2.48(2), Na1-O13 2.45(2), Na1-O16 2.49(2), Na1-N100 2.42(2), N100-Na1-S1 165.3(7), O4-Na1-O13 157.8(6), O7-Na1-O16 153.8(7).

FIG. 6. Two-dimensional coordination network of 2 with highlighting of the ${ }_{\infty}^{2}\left[\mathrm{Cu}_{5} \mathrm{I}_{6}\right]$ chains.
crystallographic screw diads of the monoclinic space group $P 2_{1}$ generates helical ${ }_{\infty}^{1}\left[\left\{\mathrm{Cu}_{5} \mathrm{I}_{6}\right\}^{-}\right]$chains that are alternatingly linked to their left and right neighbors by pairs of 1,10DT18C6 thiacrown ligands attached to Cu 2 and Cu 4 . Using the nomenclature depicted in Fig. 4, the interstrand bridging pattern may be described as $2,4: 7^{\prime}, 9^{\prime}$ for a pen-
tanuclear $\mathrm{Cu}_{5} \mathrm{I}_{5}$ backbone repeating unit. The adoption of this unusual connectivity mode coupled with the presence of severely twisted ${ }_{\infty}^{1}\left[\left\{\mathrm{Cu}_{5} \mathrm{I}_{6}\right\}^{-}\right]$pillars (Figs. 6 and 7) reduces the potential void space to such an extent that only the coordinated acetonitrile molecules cocrystallize with the iodocuprate(I)-based coordination polymer. As may be seen in Fig. 7, these solvent molecules point away from the corrugated sheets of $\mathbf{2}$, whose CuI core is effectively covered by the ionophoric 1,10DT18C6 macrocycles.

The coordination requirements of the larger potassium cations lead to the self-assembly of the two-dimensional coordination polymer $\mathbf{3}$ with its two thiacrown ligands per $\mathrm{K}^{+}$ion. This allows the adoption of an eight-fold distorted cubelike coordination sphere by the alkali atoms, in which they themselves lie on the diad axes of the monoclinic space group $P 2 / n$ (Fig. 8). In contrast to 2 , for which five thiacrown donor atoms participate in metal ion coordination, one less oxygen is required per macrocycle in the potassium iodocuprate(I) 3. As depicted in Fig. 9, the anionic pillars of this lamellar coordination polymer contain individual tetranuclear $\left[\mathrm{Cu}_{4} \mathrm{I}_{4}\right]$ units, that are linked together by bridging iodine atoms I3/I3a. The symmetry-related inner copper atoms $\mathrm{Cu} 1 / \mathrm{Cu} 1 \mathrm{a}$ of these building blocks are coordinated by S1/S1a of thiacrown ligands, whose S10/S10a sulfur atoms participate in the tetrahedral coordination spheres of the outer copper atoms $\mathrm{Cu} 2 / \mathrm{Cu} 2 \mathrm{a}$ of an adjacent iodocuprate $(\mathrm{I})$ chain. This means that the interstrand bridging mode of $\mathbf{3}$ may be described as $1,4: 2^{\prime}, 3^{\prime}$ in terms of the nomenclature introduced in Fig. 4. Inspection of Fig. 9 suggests that larger $\mathrm{Cs}^{+}$cation might possibly direct the assembly of a related $1 ; 3: 2^{\prime}, 4^{\prime}$ connectivity pattern, as this should allow five or six donor atoms of each of the participating thiacrown macrocycles in $\left[\mathrm{Cs}(1,10 \mathrm{DT} 18 \mathrm{C} 6)_{2}\right]^{+}$sandwiches to coordinate the central alkali atom.

FIG. 7. Individual iodocuprate(I) chains in $\mathbf{2}$ as viewed from the side of lamellar coordination polymer.

Selected bond lengths $(\AA)$ and angles ( ${ }^{\circ}$ ) in the eight-fold coordination sphere of K1: K1-O4 2.973(11), K1-O7 2.713(12), K1-O16 2.865(13), O4-K1-O4a 171.1(5), S1-K1-O7a 169.4(2), O16-K1-O16a 138.1(6)

## Thermal Gravimetric Analyses

A TGA/DTA trace of 2 performed at a speed of $2^{\circ} \mathrm{C} / \mathrm{min}$ reveals a mass reduction of $2.5 \%$ at $180^{\circ} \mathrm{C}$ corresponding to the loss of the coordinated acetonitrile molecule (calculated $2.8 \%$ ). This is followed by gradual loss of the bridging 1,10DT18C6 ligands between 230 and $280^{\circ} \mathrm{C}$ (weight loss $21.6 \%$, calculated $20.4 \%$ ). 2 also rapidly loses its acetonitrile molecule under vacuum at room temperature to afford a colorless solid $\mathbf{2}^{\prime}$ whose powder diffraction pattern confirms the retention of crystallinity. Its close similarity to that of $\mathbf{2}$ indicates that the integrity of the lamellar host network
is retained on loss of the solvent molecules, which subsequently can be reimbibed by covering 2 with acetonitrile. A thermal stability range comparable to that of 2 is observed for the neutral lamellar coordination polymer $\mathbf{1}$ whose network loses its bridging thiacrown macrocycles between 240 and $280^{\circ} \mathrm{C}$ (weight loss $59.4 \%$, calculated $60.9 \%$ ).

## CONCLUSIONS

Our studies demonstrate that a new class of lamellar coordination polymers with ion-ligating properties can be constructed by reaction of copper(I) iodide CuI with the thiacrown ether 1,10DT18C6 in the presence of an alkali metal iodide MI. A decisive influence of the structure-directing alkali cation $M^{+}$on both the stoichiometry and connectivity pattern of the resulting lamellar coordination polymer is apparent for ${ }_{\infty}^{2}\left[\left\{\mathrm{Na}\left(\mathrm{CH}_{3} \mathrm{CN}\right)\right\}\left\{\mathrm{Cu}_{5} \mathrm{I}_{6}\right.\right.$ (1,10DT18C6) $\}]$ (2) and ${ }_{\infty}^{2}\left[\mathrm{~K}\left\{\mathrm{Cu}_{4} \mathrm{I}_{5}(1,10 \mathrm{DT} 18 \mathrm{C} 6)_{2}\right\}\right]$ (3). However, both compounds contain one-dimensional iodocuprate(I) ribbons with infinite or oligomeric CuI double chains as characteristic substructures. This state of affairs underlines the ability of such copper(I) halides to generate complementary building units in coordination polymers that are tailored to meet both the charge and spacial requirements of their partner bridging ligands, in these cases complex $\left[\mathrm{M}(1,10 \mathrm{DT} 18 \mathrm{C} 6)_{n}\right]^{+}$cations.

As the thiacrown 1,10DT18C6 contains a total of six donor atoms for alkali cation $(2 \times \mathrm{S}, 4 \times \mathrm{O})$ it should be well-suited to coordinate the larger alkali cations $\mathrm{Rb}^{+}$and $\mathrm{Cs}^{+}$in lamellar compounds of the type ${ }_{\infty}^{2}\left[M\left\{\mathrm{Cu}_{x} \mathrm{I}_{x+1}\right.\right.$ ( $\left.\left.1,10 \mathrm{DT} 18 \mathrm{C} 6)_{2}\right\}\right]$ and studies on the preparation of such coordination polymers are currently in progress. Attempts to exchange $\mathrm{K}^{+}$in $\mathbf{3}$ by other cations have, as yet, proved unsuccessful.
