#### Abstract

Two new aluminotriphosphates, $\mathrm{RbAl}_{3}\left(\mathrm{P}_{3} \mathrm{O}_{10}\right)_{2}$ and $\mathrm{CsAl}_{3}\left(\mathrm{P}_{3} \mathrm{O}_{10}\right)_{2}$, were synthesized by solid-state reaction. They crystallize in non-centrosymmetric space groups: $C 222_{1}$ with $a=9.8757(7) \AA, b=12.8854(10) \AA, c=11.9192(7) \AA,(Z=4)$ for $\operatorname{RbAl}_{3}\left(\mathrm{P}_{3} \mathrm{O}_{10}\right)_{2}$ and $C 2 c e$ with $a=10.0048(7) \AA, b=13.3008(10) \AA, c=12.1698(7) \AA,(Z=4)$ for $\mathrm{CsAl}_{3}\left(\mathrm{P}_{3} \mathrm{O}_{10}\right)_{2}$. Their 3D frameworks, built up of corner sharing $\mathrm{P}_{3} \mathrm{O}_{10}$ groups, $\mathrm{AlO}_{4}$ tetrahedra and $\mathrm{AlO}_{6}$ octahedra, exhibit several remarkable features. The $\mathrm{AlO}_{4}$ tetrahedra and $\mathrm{P}_{3} \mathrm{O}_{10}$ groups are directly associated through the corners, forming helical columns in the Rb-phase and "helicoid" layers in the Csphase. The simultaneous presence of $\mathrm{AlO}_{4}$ and $\mathrm{AlO}_{6}$ species, rather rare in phosphates, leads to the formation of closely related $\left[\mathrm{Al}_{3} \mathrm{P}_{6} \mathrm{O}_{24}\right]_{\infty}$ layers in both structures, which differ by their stacking mode. The presence of intersecting tunnels running along $\langle 110\rangle$ and [001] directions, with $\mathrm{Rb}^{+}$and $\mathrm{Cs}^{+}$sitting at the intersections, shows the opened character of these two structures. ## 1. Introduction

The great ability of aluminium to accommodate several coordinations-tetrahedral, octahedral and even bipyramidal-involves that its association with elements that can only adopt a tetrahedral coordination, like silicon or phosphorus, allows the formation of opened frameworks in oxides. Consequently, aluminosilicates and aluminophosphates have been the purpose of numerous studies in view of various applications in the fields of catalysis and separation [1-4 and references therein]. Compared to aluminosilicates, aluminophosphates are much less numerous if one except the organically templated aluminophosphates, the hydroxyphosphates and hydrates, and they have the advantage to be synthesized at lower temperature.

[^0]Moreover, several studies of monazites and apatites $[5,6]$ show that phosphates can also constitute a valuable crystalline matrix for the storage of nuclear wastes, suggesting that the exploration of aluminophosphates with an opened framework, susceptible to accommodate radiative cations like cesium, is of great importance.

Our previous investigation of the $\mathrm{Cs}-\mathrm{Al}-\mathrm{P}-\mathrm{O}$ system, which led to the triphosphate $\mathrm{Cs}_{2} \mathrm{AlP}_{3} \mathrm{O}_{10}$ [7], was based on the above considerations of the potential of aluminophosphate frameworks. In the latter aluminophosphate, aluminium behaves as a "normal" cation and exhibits the octahedral coordination, so that in this layer structure, the triphosphate groups are interconnected through $\mathrm{AlO}_{6}$ octahedra. At this point of the knowledge of the $\mathrm{Cs}-\mathrm{Al}-\mathrm{P}-\mathrm{O}$ system, it is vital to consider the possibility to introduce tetrahedral species concomitantly with the $\mathrm{PO}_{4}$ tetrahedra, in order to form mixed tetrahedral frameworks like in zeolites. The recent synthesis of the aluminophosphate
$\mathrm{NaCs}{ }_{2} \mathrm{Al}\left(\mathrm{PO}_{4}\right)_{2}$ [8], whose structure consists of vertexsharing $\mathrm{AlO}_{4}$ and $\mathrm{PO}_{4}$ tetrahedra forming a 3D $\left[\mathrm{AlP}_{2} \mathrm{O}_{8}\right]_{\infty}$ framework, suggests that such a feature appears for smaller $\mathrm{P} / \mathrm{Al}$ molar ratio, i.e., 2 instead of 3 for the first $\mathrm{Cs}_{2} \mathrm{AlP}_{3} \mathrm{O}_{10}$ phosphate. We have revisited the systems $\mathrm{Cs}-\mathrm{Al}-\mathrm{P}-\mathrm{O}$ and $\mathrm{Rb}-\mathrm{Al}-\mathrm{P}-\mathrm{O}$, involving $\mathrm{P} / \mathrm{Al}$ ratio $\leqslant 2$. We describe herein two new aluminophosphates, $\mathrm{RbAl}_{3}\left(\mathrm{P}_{3} \mathrm{O}_{10}\right)_{2}$ and $\mathrm{CsAl}_{3}\left(\mathrm{P}_{3} \mathrm{O}_{10}\right)_{2}$, which exhibit closely related original intersecting tunnel structures, both built up of corner-sharing $\mathrm{AlO}_{6}$ octahedra, $\mathrm{AlO}_{4}$ tetrahedra and triphosphate groups $\mathrm{P}_{3} \mathrm{O}_{10}$ and we emphasize the great ability of $\mathrm{AlO}_{4}$ and $\mathrm{P}_{3} \mathrm{O}_{10}$ units to share corners, forming helical columns in the Rb-phase and "helicoid" layers in the Cs-phase.

## 2. Experimental

### 2.1. Synthesis and crystal growth

The single crystals used for the structures determinations of $\mathrm{RbAl}_{3}\left(\mathrm{P}_{3} \mathrm{O}_{10}\right)_{2}$ and $\mathrm{CsAl}_{3}\left(\mathrm{P}_{3} \mathrm{O}_{10}\right)_{2}$ were extracted from preparations synthesized in two steps at the stoichiometric compositions ( $\mathrm{Rb}(\mathrm{Cs}): \mathrm{Al}: \mathrm{P}=1: 3: 6)$. The first step consisted in heating up at approximately 770 K during a few hours in air the beforehand finely ground mixture of $\mathrm{Al}_{2} \mathrm{O}_{3}$ (Carlo Erba $99 \%$ ), $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{HPO}_{4}$ (Prolabo Normapur $99.5 \%$ ) and $A \mathrm{NO}_{3}(A=\mathrm{Rb}, \mathrm{Cs}$; Chempur $99.9 \%$ ) placed in a platinum crucible. The so obtained whitish powders were then finely ground again in an agate mortar. In a second step, the cesium aluminium mixture was placed in a platinum crucible and heated up during 24 h at 1173 K , then slowly cooled down to 1093 K for 48 h . For the rubidium-aluminium phosphate, the powder was placed in a silica tube, which was evacuated and sealed. It was heated up at 1123 K for 20 h then cooled at $1 \mathrm{~K} / \mathrm{h}$ down to 1103 K and at $10 \mathrm{~K} / \mathrm{h}$ down to 1003 K .

Attempts to synthesize these two aluminophosphates in the form of polycrystalline samples confirmed the formation of the latter as the major phase. Nevertheless, careful X-ray powder characterization revealed the presence in the samples of minor impurity phases.

### 2.2. Powder $X$-ray diffraction studies

The X-ray powder diffraction patterns of these triphosphates were registered with a PHILIPS PW 1830 diffractometer using the $\mathrm{CuK} \alpha$ radiation. For $\mathrm{RbAl}_{3}\left(\mathrm{P}_{3} \mathrm{O}_{10}\right)_{2}$, the $2 \theta$ angle ranged from $5^{\circ}$ to $100^{\circ}$ with a step of $0.02^{\circ}$ and 9.8 s per step. For $\mathrm{CsAl}_{3}\left(\mathrm{P}_{3} \mathrm{O}_{10}\right)_{2}$, the $2 \theta$ angle ranged from $5^{\circ}$ to $85^{\circ}$ with a step of $0.02^{\circ}$ and with 12 s per step. The cell parameters were refined in pattern matching mode with the program FullProf [9]. Most of the diffraction peaks were indexed in orthorhombic cells compatible with those determined from
the single crystals studies, with $a=10.0214(5) \AA, b=$ $13.3292(7) \AA, c_{\circ}=12.1873(6) \AA$ for the cesium phase and $a=9.8849(3) \AA, b=12.9032(4) \AA, c=11.9279(4) \AA$ for the rubidium phase. However, these refinements revealed the existence of a few non-indexed peaks, corresponding to the presence of at least one secondary unidentified phase.

### 2.3. Crystal studies

The semi-quantitative analyses of the colourless crystals extracted from the two preparations were performed with an OXFORD 6650 microprobe mounted on a PHILIPS XL30 FEG scanning electron microscope. The obtained cationic compositions were in agreement with the expected theoretical values of "10:30:60", respectively, for the alkali, metallic and phosphorus cations.

Several crystals were then optically selected to be tested. The dimension of the two single crystals that were chosen for the structure determinations and refinements are reported in Table 1. The data were collected with a Bruker-Nonius Kappa CCD four-circle diffractometer using the Mo $K \alpha$ radiation, equipped with a bidimensional CCD detector fixed at a distance of 34 mm from the crystals. Different strategies using $\varphi$ and $\omega$ scans were determined, according to the size of the crystals (Table 1). The cell parameters reported in Table 1 were accurately determined from the whole registered frames. Data were reduced and corrected for Lorentz and polarization effects with the EvalCCD package [10]. Structure determinations and refinements for the two compounds were performed with the JANA2000 program [11].

For the rubidium phosphate, the observed systematic absences $h k l: h+k=2 n+1$ and $00 l: l=2 n+1$ correspond to the non-centrosymmetric space group $C 222_{1}$ (no. 20). The structure of $\mathrm{RbAl}_{3}\left(\mathrm{P}_{3} \mathrm{O}_{10}\right)_{2}$ was determined using the heavy atom method and then successive difference Fourier synthesis and Fourier synthesis. Absorption and secondary extinction effects corrections were applied. The refinement of the atomic coordinates and of the anisotropic thermal parameters of all atoms led to the reliability factors $R=0.0371$ and $R_{\mathrm{w}}=$ 0.0324 (Table 1) and to the atomic parameters listed in Table 2a. The value of Flack parameter was $-0.004(9)$, confirming that the crystal was not twined by inversion. Note that, as expected, the solution corresponding to the enantiomorphic structure led to higher reliability factors $\left(R=0.0772\right.$ and $\left.R_{\mathrm{w}}=0.0954\right)$.

Two other crystals of this phosphate have been studied in order to check the possible existence of a crystal presenting the enantiomorphic structure. They both have the same structure than the first one, with Flack parameters of $-0.002(13)$ and $0.032(8)$, respectively.

For $\mathrm{CsAl}_{3}\left(\mathrm{P}_{3} \mathrm{O}_{10}\right)_{2}$, the studied crystal presented the observed systematic extinction conditions $h k l: h+k=$ $2 n+1, h k 0: h=2 n+1, k=2 n+1$ and $h 0 l: l=2 n+$ 1 , which are consistent either with the centrosymmetric space group Cmce (\# 64) or the non-centrosymmetric space group C2ce (\#41). The structure was solved in the non-centrosymmetric C2ce space group. The structure of $\mathrm{CsAl}_{3}\left(\mathrm{P}_{3} \mathrm{O}_{10}\right)_{2}$ was determined using the heavy atom method and successive difference synthesis and Fourier synthesis. Absorption and secondary extinction effect corrections were applied. The refinement of the atomic coordinates and of the anisotropic thermal parameters of all atoms lead to the reliability factors $R=0.0314$ and $R_{\mathrm{w}}=0.0318$ (Table 1) and to the atomic parameters listed in Table 2b.

Further details of the crystal structure investigations (including the anisotropic thermal parameters) can be obtained from the Fachinformationszentrum Karlsruhe, 76344 Eggenstein-Leopoldshafen, Germany, (fax: (49) 7247-808-666; e-mail: crysdata@fiz-karlsruhe.de) on
quoteing the depositery number CSD-414552 and CSD-414553 for $\mathrm{RbAl}_{3}\left(\mathrm{P}_{3} \mathrm{O}_{10}\right)_{2}$ and $\mathrm{CsAl}_{3}\left(\mathrm{P}_{3} \mathrm{O}_{10}\right)_{2}$ respectively.

## 3. Results and discussion

Both aluminophosphates exhibit a 3D framework [ $\left.\mathrm{Al}_{3} \mathrm{P}_{6} \mathrm{O}_{20}\right]_{\infty}$ built up of corner sharing $\mathrm{AlO}_{6}$ octahedra, $\mathrm{AlO}_{4}$ tetrahedra and triphosphate $\mathrm{P}_{3} \mathrm{O}_{10}$ groups, forming intersecting tunnels. Though closely related, these structures are significantly different.

### 3.1. Description of the $\operatorname{RbAl}_{3}\left(P_{3} O_{10}\right)_{2}$ host-lattice

The projections of the structure along [001] (Fig. 1) and along [110] (Fig. 2) show that the triphosphate groups and the $\mathrm{AlO}_{4}$ and $\mathrm{AlO}_{6}$ polyhedra form six-sided tunnels running along [001] and [110], respectively, and that the rubidium cations sit at the intersection of these

All atoms were refined anisotropically and are given in the form of the isotropic equivalent displacement parameter $U_{\text {eq }}$ defined by $U_{\text {eq }}=$ $\frac{1}{3} \sum_{i=1}^{3} \sum_{j=1}^{3} U_{i j} a^{* i} a^{* j} \vec{a}_{i} \vec{a}_{j}$.
tunnels. Note that, similarly, six-sided tunnels run along [ $1 \overline{1} 0]$, which intersect the two other types of tunnels at the $\mathrm{Rb}^{+}$site. But the most important characteristic of this structure deals with the fact that the $\mathrm{AlO}_{4}$ tetrahedra share their vertices with the triphosphate groups, forming isolated $\left[\mathrm{AlP}_{6} \mathrm{O}_{20}\right]_{\infty}$ tetrahedral columns running along $\vec{c}$ (Fig. 1). The perspective view of these columns along [010] (Fig. 3a) shows that they exhibit a helical character. One $\left[\mathrm{AlP}_{6} \mathrm{O}_{20}\right]_{\infty}$ tetrahedral column can indeed be described as the interlacement of two $\left[\mathrm{AlP}_{3} \mathrm{O}_{12}\right]_{\infty}$ helical chains around the $2_{1}$ screw axis parallel to the $\vec{c}$ direction. In each chain, one $\mathrm{AlO}_{4}$ alternates with one $\mathrm{P}_{3} \mathrm{O}_{10}$ group, and two chains share their $\mathrm{AlO}_{4}$ tetrahedra to form the $\left[\mathrm{AlP}_{6} \mathrm{O}_{20}\right]_{\infty}$ tetrahedral columns. The entire $\left[\mathrm{Al}_{3} \mathrm{P}_{6} \mathrm{O}_{20}\right]_{\infty}$ framework results

from the assembly of helical $\left[\mathrm{AlP}_{6} \mathrm{O}_{20}\right]_{\infty}$ columns of tetrahedra through $\mathrm{AlO}_{6}$ octahedra (Fig. 1).

### 3.2. Description of the $\mathrm{CsAl}_{3}\left(P_{3} O_{10}\right)_{2}$ host-lattice

The projections of the structure of this phase along [001] (Fig. 4) and along [110] (Fig. 5) show that, like in $\mathrm{RbAl}\left(\mathrm{P}_{3} \mathrm{O}_{10}\right)_{2}$, the triphosphate groups share their apices with $\mathrm{AlO}_{4}$ and $\mathrm{AlO}_{6}$ polyhedra. However, differently from $\mathrm{RbAl}\left(\mathrm{P}_{3} \mathrm{O}_{10}\right)_{2}$, the $\mathrm{P}_{3} \mathrm{O}_{10}$ and $\mathrm{AlO}_{4}$ species do not form isolated columns, but tetrahedral $\left[\mathrm{AlP}_{6} \mathrm{O}_{20}\right]_{\infty}$ layers parallel to the (100) plane (Fig. 4). The perspective view of such a tetrahedral $\left[\mathrm{AlP}_{6} \mathrm{O}_{20}\right]_{\infty}$ layer (Fig. 6a) shows that it also presents some helical elements: two $\mathrm{P}_{3} \mathrm{O}_{10}$ groups and one $\mathrm{AlO}_{4}$ tetrahedron are indeed connected to form $\left[\mathrm{AlP}_{6} \mathrm{O}_{22}\right]$ helical groups (Fig. 6b). Each $\mathrm{AlO}_{4}$ tetrahedron of one helical $\left[\mathrm{AlP}_{6} \mathrm{O}_{22}\right]$ group is linked to two other $\left[\mathrm{AlP}_{6} \mathrm{O}_{22}\right]$ groups to form the $\left[\mathrm{AlP}_{6} \mathrm{O}_{20}\right]_{\infty}$ tetrahedral layer. Note that similar $\left[\mathrm{AlP}_{6} \mathrm{O}_{22}\right]$ groups are observed in the $\left[\mathrm{AlP}_{6} \mathrm{O}_{20}\right]_{\infty}$ tetrahedral columns described above for $\mathrm{RbAl}_{3}\left(\mathrm{P}_{3} \mathrm{O}_{10}\right)_{2}$.

Fig. 3. Perspective view showing the helical character of the $\left[\mathrm{AlP}_{6} \mathrm{O}_{20}\right]_{\infty}$ tetrahedral column running along the [001] direction in $\mathrm{RbAl}_{3}\left(\mathrm{P}_{3} \mathrm{O}_{10}\right)_{2}$. The two interlaced $\left[\mathrm{AlP}_{3} \mathrm{O}_{12}\right]_{\infty}$ chains are shown (continuous and dotted lines). One [ $\left.\mathrm{AlP}_{6} \mathrm{O}_{22}\right]$ tetrahedral building unit of the $\left[\mathrm{AlP}_{6} \mathrm{O}_{20}\right]_{\infty}$ column is emphasized (bold lines).

Fig. 5. Projection along [110] of the structure of $\mathrm{CsAl}_{3}\left(\mathrm{P}_{3} \mathrm{O}_{10}\right)_{2}$.
Nevertheless, in these columns two successive $\left[\mathrm{AlP}_{6} \mathrm{O}_{22}\right]$ units are deduced one from the other through the $2_{1}$ screw axis parallel to the [001] direction (Fig. 3), whereas the $\left[\mathrm{AlP}_{6} \mathrm{O}_{22}\right]$ units are related through the $n$ glide mirror in a $\left[\mathrm{AlP}_{6} \mathrm{O}_{20}\right]_{\infty}$ layer. The entire $\left[\mathrm{Al}_{3} \mathrm{P}_{6} \mathrm{O}_{20}\right]_{\infty}$ framework results from the association of the $\left[\mathrm{AlP}_{6} \mathrm{O}_{20}\right]_{\infty}$ tetrahedral layers through single $\mathrm{AlO}_{6}$ octahedra (Fig. 4). The 3D $\left[\mathrm{Al}_{3} \mathrm{P}_{6} \mathrm{O}_{20}\right]_{\infty}$ framework delimits also intersecting tunnels running along the [001] and $\langle 110\rangle$ directions (Figs. 4 and 5) and the $\mathrm{Cs}^{+}$cations sit at the intersections of these tunnels. The shape of the six-sided $\langle 110\rangle$ tunnels (Fig. 5) is rather similar to that observed in the Rb -phase, whereas the five-sided [001] tunnels of the Cs-phase (Fig. 4) are very different from the sixsided [001] tunnels of the Rb-phosphate (Fig. 1).

### 3.3. Relationships between the $\operatorname{RbAl}_{3}\left(P_{3} O_{10}\right)_{2}$ and $\mathrm{CsAl}_{3}\left(\mathrm{P}_{3} \mathrm{O}_{10}\right)_{2}$ host-lattices

In spite of the different arrangements of their $\mathrm{AlO}_{4}$ and $\mathrm{PO}_{4}$ tetrahedra, the $\left[\mathrm{Al}_{3} \mathrm{P}_{6} \mathrm{O}_{20}\right]_{\infty} 3 \mathrm{D}$ frameworks of these two triphosphates exhibit close relationships. The latter are clearly evidenced by comparing the projections of these structures along [110] (Figs. 2 and 5). One indeed observes that each of these structures can be described by the stacking along $\vec{c}$ of identical $\left[\mathrm{Al}_{3}\right.$ $\left.\mathrm{P}_{6} \mathrm{O}_{24}\right]_{\infty}$ layers. The projections of these $\left[\mathrm{Al}_{3} \mathrm{P}_{6} \mathrm{O}_{24}\right]_{\infty}$ layers along $\vec{c}$ show their great similarity. In both cases, Rb-phase (Fig. 7a) and Cs-phase (Fig. 7b), the $\mathrm{AlO}_{6}$ octahedra are displayed on an approximately square array and joined through $\mathrm{PO}_{4}$ tetrahedra to form $\left[\mathrm{Al}_{2} \mathrm{P}_{4} \mathrm{O}_{22}\right]$ rings, which are overhung by $\left[\mathrm{AlP}_{2} \mathrm{O}_{10}\right]$ bridges. Thus, similar six-sided, five-sided and dia-mond-shape windows are observed for the two types of layers. The main difference between these two layers deals with the configuration of the $\left[\mathrm{Al}_{2} \mathrm{P}_{4} \mathrm{O}_{22}\right]$ rings and

Fig. 6. (a) Perspective view of one $\left[\mathrm{AlP}_{6} \mathrm{O}_{20}\right]_{\infty}$ tetrahedral layer parallel to the (100) plane, showing its helicoïdal character. (b) The " $\mathrm{AlP}_{6} \mathrm{O}_{22}$ " helical unit encountered in the $\left[\mathrm{AlP}_{6} \mathrm{O}_{20}\right]_{\infty}$ tetrahedral layers of $\mathrm{CsAl}_{3}\left(\mathrm{P}_{3} \mathrm{O}_{10}\right)_{2}$ and in the $\left[\mathrm{AlP}_{6} \mathrm{O}_{20}\right]_{\infty}$ tetrahedral columns of $\mathrm{RbAl}_{3}\left(\mathrm{P}_{3} \mathrm{O}_{10}\right)_{2}$.
[ $\mathrm{AlP}_{2} \mathrm{O}_{10}$ ] bridges, which make that the windows are significantly more opened in the Cs-triphosphate (Fig. 7b) than in the Rb-triphosphate (Fig. 7a). The stacking of the $\left[\mathrm{Al}_{3} \mathrm{P}_{6} \mathrm{O}_{24}\right]_{\infty}$ layers along $\vec{c}$ in the Rb -phase is thus different from the one observed in the Cs-phase: two successive layers are deduced one from the other by $2_{1}$ screw axis in the first one (Fig. 2), whereas they correspond through a $c$ glide mirror in the second one (Fig. 5). Due to these different stacking modes, one observes twice more five-sided tunnels running along $\vec{c}$ in the Cs-phosphate (Fig. 4), than six-sided tunnels along that direction in the Rb -phosphate (Fig. 1). Moreover, the $\langle 110\rangle$ tunnels are aligned along the $\vec{c}$

Fig. 7. Projection of one $\left[\mathrm{Al}_{3} \mathrm{P}_{6} \mathrm{O}_{24}\right]_{\infty}$ layer parallel to the (001) plane observed (a) in $\mathrm{RbAl}_{3}\left(\mathrm{P}_{3} \mathrm{O}_{10}\right)_{2}$ and (b) in $\mathrm{CsAl}_{3}\left(\mathrm{P}_{3} \mathrm{O}_{10}\right)_{2}$.
direction in the Rb-phase (Fig. 2), whereas they form staggered rows along that direction in the Cs-phase (Fig. 5).

### 3.4. Comparison with other triphosphates

One important characteristic of these two compounds deals with the fact that their framework is built up of triphosphate groups. The latter seems to be currently observed in phosphates involving hydroxyl groups and water molecules. In contrast, only nine different types of "non-containing hydrogen atoms" host-lattices with triphosphate groups have been synthesized to date to our knowledge. Five of them contain only $\mathrm{P}_{3} \mathrm{O}_{10}$ groups: $A \mathrm{Be}_{2} \mathrm{P}_{3} \mathrm{O}_{10}\left(A=\mathrm{Rb}, \mathrm{NH}_{4}\right)$ [12,13], $\mathrm{KThP}_{3} \mathrm{O}_{10}$ [14], $\mathrm{Na}_{5} \mathrm{P}_{3} \mathrm{O}_{10} \quad[15-17], \operatorname{Li} M_{2} \mathrm{P}_{3} \mathrm{O}_{10} \quad(M=\mathrm{Co}, \mathrm{Ni}) \quad[18,19]$ and $\operatorname{Cs} M \mathrm{P}_{3} \mathrm{O}_{10}$ with $M=\mathrm{Ga}, \mathrm{Al}, \mathrm{Cr}[7]$. The four others can be described as mixed phosphates containing simultaneously $\mathrm{P}_{3} \mathrm{O}_{10}$ and $\mathrm{PO}_{4}$ groups as in $\mathrm{U}_{2} \mathrm{P}_{3} \mathrm{O}_{10}\left(\mathrm{PO}_{4}\right)$ [20] and $\mathrm{CsTa}_{2} \mathrm{P}_{3} \mathrm{O}_{10}\left(\mathrm{PO}_{4}\right)_{2}$ [21] or $\mathrm{P}_{3} \mathrm{O}_{10}$ and $\mathrm{P}_{2} \mathrm{O}_{7}$ groups as in $\mathrm{Na}_{7} \mathrm{Y}_{2} \mathrm{P}_{3} \mathrm{O}_{10}\left(\mathrm{P}_{2} \mathrm{O}_{7}\right)_{2}$ [22] and $A \mathrm{M}_{6} \mathrm{P}_{3} \mathrm{O}_{10}\left(\mathrm{P}_{2} \mathrm{O}_{7}\right)_{2}$ with $A=\mathrm{NH}_{4}, \mathrm{~K}, \mathrm{Na}, \mathrm{Ag}$ and $M=\mathrm{Cd}, \quad \mathrm{Mn}[23,24]$. Remarkably, $\mathrm{RbAl}_{3}\left(\mathrm{P}_{3} \mathrm{O}_{10}\right)_{2}$

(helicoïdal $\left[\mathrm{AlP}_{6} \mathrm{O}_{20}\right]_{\infty}$ layers) tetrahedral frameworks, whereas a 3D-tetrahedral framework built up of $\mathrm{BeO}_{4}$ and $\mathrm{P}_{3} \mathrm{O}_{10}$ species is obtained for $A \mathrm{Be}_{2} \mathrm{P}_{3} \mathrm{O}_{10}$ phases. This different behaviour of aluminium triphosphates compared to the beryllium triphosphates is easily explained by the ability of aluminium to adopt both tetrahedral and octahedral coordinations. The presence in the same framework of two different kinds of polyhedra for aluminium together with triphosphates
is also a remarquable feature. Most of the nonorganically templated and non-fluorinated phosphates presenting such structural characteristic contain water molecules and/or hydroxyl groups. To our knowledge, there are only two "non-containing hydrogen atoms" aluminium phosphates with this characteristic: $\mathrm{Mg}_{6} \mathrm{Si}_{2} \mathrm{Al}_{22} \mathrm{P}_{26} \mathrm{O}_{112}$, with aluminium atoms in octahedral and tetrahedral coordinations [25] and $\mathrm{NaRb}_{2} \mathrm{Al}_{2}$ $\left(\mathrm{PO}_{4}\right)_{3}$, involving $\mathrm{AlO}_{4}$ and $\mathrm{AlO}_{5}$ polyhedra [8].

### 3.5. Configuration of the $P_{3} O_{10}$ groups and interatomic distances

The previous studies of the triphosphates have shown the great flexibility of the $\mathrm{P}_{3} \mathrm{O}_{10}$ groups, whose geometry depends on the mode of connection of the latter with the surrounding octahedra and tetrahedra.

In the two present phases, both $\mathrm{P}_{3} \mathrm{O}_{10}$ groups exhibit a similar geometry. The average values for the $\mathrm{P}-\mathrm{P}$ distances $(2.88 \AA)$ and the $\mathrm{P}-\mathrm{P}-\mathrm{P}$ angles $\left(124^{\circ}\right)$ are intermediate between the limit values observed in the literature for triphosphate groups in different compounds. One generally observes $\mathrm{P}-\mathrm{P}$ distances ranging from 2.76 to $3.05 \AA$, whereas the $\mathrm{P}-\mathrm{P}-\mathrm{P}$ angles may vary from $80^{\circ}$ when the $\mathrm{P}_{3} \mathrm{O}_{10}$ group share three apices with the same octahedron, to $151^{\circ}$ when each $\mathrm{PO}_{4}$ tetrahedron is linked to a different coordination polyhedron of the framework [7,15-17,26]. In the present phases, the fact that each $\mathrm{P}_{2} \mathrm{O}_{7}$ group belonging to the $\mathrm{P}_{3} \mathrm{O}_{10}$ groups shares two apices with the same $\mathrm{AlO}_{6}$ octahedron induces $\mathrm{P}-\mathrm{P}-\mathrm{P}$ angles smaller than $151^{\circ}$, i.e., of ca. $124^{\circ}$.

The geometry of the $\mathrm{PO}_{4}$ tetrahedra is close to that generally observed. Two groups of distances can be distinguished. The $\mathrm{P}-\mathrm{O}$ bonds corresponding to the two $\mathrm{P}-\mathrm{O}-\mathrm{P}$ bridges of the $\mathrm{P}_{3} \mathrm{O}_{10}$ groups are the largest one (ranging from $1.5757(15)$ to $1.640(2) \AA$ ) (Table 3). Consequently, the two "external" tetrahedra $\mathrm{P}(1)$ and $\mathrm{P}(3)$ present one long $\mathrm{P}-\mathrm{O}$ distance (from 1.6084(14) to $1.640(2) \AA$ ) and three smaller ones (from 1.4702(18) to $1.536(3) \AA)$, whereas the "central" $\mathrm{P}(2)$ tetrahedron has two long $\mathrm{P}-\mathrm{O}$ distances (from 1.5757(15) to $1.5945(14) \AA$ ) and two shorter ones (from 1.477(2) to $1.4963(14) \AA$ ) (Table 3).

The $\mathrm{AlO}_{4}$ and $\mathrm{AlO}_{6}$ polyhedra are quite regular with $\mathrm{Al}-\mathrm{O}$ distances ranging from $1.7113(17)$ to $1.7518(17) \AA$ in the Al tetrahedra, and from $1.8462(14)$ to $1.9142(18)$ in the Al octahedra.

The rubidium cations exhibit an eight-fold coordination with $\mathrm{Rb}-\mathrm{O}$ distances ranging from $2.958(3)$ to $3.306(2) \AA$ (Table 3a), whereas the cesium cations are environed by ten oxygen atoms with significantly longer $\mathrm{Cs}-\mathrm{O}$ distances, ranging from $3.0271(19)$ to $3.594(2) \AA$ (Table 3b).

## 4. Conclusion

Aluminophosphates involving simultaneously triphosphate groups, $\mathrm{AlO}_{4}$ tetrahedra and $\mathrm{AlO}_{6}$ octahedra have been synthesized for the first time. More importantly, this study shows the exceptional ability of such aluminotriphosphates to form 1D and 2D "Al-P-O" tetrahedral frameworks with an original helical geometry. This suggests that numerous "Al-P-O" tetrahedral frameworks remain to be dis-
covered and that it should be possible to control their dimensionality by the introduction of $\mathrm{AlO}_{6}$ octahedra.

## Acknowledgments

Authors want to thank Drs. O. Pérez and S. Marinel for their friendly collaboration to this work.
