## Abstract

Attempts to prepare alkaline metal uranyl niobates of composition  $A_{1-x}\text{UNbO}_{6-x/2}$  by high-temperature solid-state reactions of  $\text{A}_2\text{CO}_3$ ,  $\text{U}_3\text{O}_8$  and  $\text{Nb}_2\text{O}_5$  led to pure compounds for  $x = 0$  and  $A = \text{Li}$  (**1**),  $\text{Na}$  (**2**),  $\text{K}$  (**3**),  $\text{Cs}$  (**4**) and for  $x = 0.5$  and  $A = \text{Rb}$  (**5**),  $\text{Cs}$  (**6**). Single crystals were grown for **1**, **3**, **4**, **5**, **6** and for the mixed  $\text{Na}_{0.92}\text{Cs}_{0.08}\text{UNbO}_6$  (**7**) compound. Crystallographic data: **1**, monoclinic,  $P2_1/c$ ,  $a = 10.3091(11)$ ,  $b = 6.4414(10)$ ,  $c = 7.5602(5)$  Å,  $\beta = 100.65(1)$ ,  $Z = 4$ ,  $R_1 = 0.054$  ( $wR_2 = 0.107$ ); **3**, **5** and **7** orthorhombic,  $Pnma$ ,  $Z = 8$ , with  $a = 10.307(2)$ ,  $10.272(4)$  and  $10.432(3)$  Å,  $b = 7.588(1)$ ,  $7.628(3)$  and  $7.681(2)$  Å,  $c = 13.403(2)$ ,  $13.451(5)$  and  $13.853(4)$  Å,  $R_1 = 0.023$ ,  $0.046$  and  $0.036$  ( $wR_2 = 0.058$ ,  $0.0106$  and  $0.088$ ) for **3**, **5** and **7**, respectively; **6**, orthorhombic,  $Cmcm$ ,  $Z = 8$ , and  $a = 13.952(3)$ ,  $b = 10.607(2)$  Å,  $c = 7.748(2)$  Å,  $R_1 = 0.044$  ( $wR_2 = 0.117$ ).

The crystal structure of **1** is characterized by  ${}^2_{\infty}[\text{UNbO}_6]^-$  layers of uranophane sheet anion topology parallel to the (100) plane. These layers are formed by the association by edge-sharing of  ${}^1_{\infty}[\text{UO}_5]^{4-}$  chains of edge-shared  $\text{UO}_7$  pentagonal bipyramids and  ${}^1_{\infty}[\text{NbO}_4]^{3-}$  chains of corner-shared  $\text{NbO}_5$  square pyramids alternating along the [010] direction. The  $\text{Li}^+$  ions are located between two consecutive layers and hold them together; the  $\text{Li}^+$  ions and two layers constitute a neutral “sandwich”  $\{(\text{UNbO}_6)^-(\text{Li})_2^+(\text{UNbO}_6)^-\}$ . In this unusual structure, the neutral sandwiches are stacked one above another with no formal chemical bonds between the neutral sandwiches.

The homeotypic compounds **3**, **5**, **6**, **7** have open-framework structures built from the association by edge-sharing in two directions of parallel  ${}^1_{\infty}[\text{UO}_5]^{4-}$  chains of edge-shared  $\text{UO}_7$  pentagonal bipyramids and  ${}^1_{\infty}[\text{Nb}_2\text{O}_8]^{6-}$  ribbons of two edge-shared  $\text{NbO}_6$  octahedra further linked by corners. In **3**, **5** and **7**, the mono-dimensional large tunnels created in the [001] direction by this arrangement can be considered as the association by rectangular faces of two columns of triangular face-shared trigonal prisms of uranyl oxygens. In **3** and **7**, all the trigonal prisms are occupied by the alkaline metal, in **5**, they are half-occupied. In **6**, the polyhedral arrangement is more symmetric and the tunnels created in the [010] direction are built of face-sharing cubes of uranyl oxygens totally occupied by the Cs atoms. This last compound well illustrates the structure-directing effect of the concenterion.

## 1. Introduction

As a part of the ongoing research on the synthesis and the crystal structure studies of compounds obtained from the condensation of uranyl bipyramidal polyhedra (square, pentagonal or hexagonal bipyramids) and oxoanions such as silicate [1–3], phosphate [4–6], molybdate [7–16] or tungstate [17–20], recent studies in our group have focused

on the uranyl–vanadate system [21–28]. Surprisingly, no recent report concern the uranyl niobates although some similarities exist between the U–V–O and U–Nb–O systems. For example,  $\text{UMO}_5$  and  $\text{UM}_3\text{O}_{10}$  that contain  $\text{U}^{5+}$  adopt the same structures for both  $M = \text{V}$  [29–32] and  $\text{Nb}$  [33–35]. In addition, some uranium–niobium-containing oxides have structures based on very common types such as perovskite in the  $A$  cation-deficient perovskite  $\text{UNb}_4\text{O}_{12}$  [36], pyrochlore in  $(\text{U, Na})_{2-x}\text{Nb}_2\text{O}_{7-y}$  [37] or tetragonal bronze in  $(\text{Nb}_{7.6}\text{U}_{2.4})(\text{Ba}_{5.2}\text{K}_{0.8})\text{O}_{30}$  [38].

Majority of the alkaline metal uranyl vanadates adopts layered structures built from the association of uranyl bipyramids and various vanadium polyhedra, tetrahedra in  $(\text{UO}_2)_3(\text{VO}_4)_2 \cdot 5\text{H}_2\text{O}$  [23], the alkaline uranyl vanadate series  $A_6\text{U}_5\text{V}_2\text{O}_{23}$  ( $A = \text{Na}, \text{K}, \text{Rb}$ ) [22,24] and the oxychloride compounds  $A_7\text{U}_8\text{V}_2\text{O}_{32}\text{Cl}$  ( $A = \text{Rb}, \text{Cs}$ ) [25], square pyramids in  $\text{CsUV}_3\text{O}_{11}$  [21] and in  $A\text{UVO}_6$ ,  $A = \text{Na}, \text{K}, \text{Rb}, \text{Cs}, \text{Ag}$  [31,39–43], a family deriving from the carnotite mineral. A three-dimensional arrangement has been recently reported in the uranyl vanadates  $A(\text{UO}_2)_4(\text{VO}_4)_3$  ( $A = \text{Li}, \text{Na}$ ) within a novel open-framework with non-crossing channels [27].

The extended inorganic architectures formed in uranyl-containing compounds are governed in part by the geometry of the oxoanion (tetrahedron, square pyramid, octahedron, etc.) but also by the alkaline cation, which plays a key role in both connectivity and dimensionality of the obtained crystal structures. For example,  $A\text{UMO}_6$  compounds have been characterized both for  $M = \text{V}$  and  $\text{Nb}$  and adopt layered structures. In  $A\text{UVO}_6$ ,  $A = \text{Na}, \text{K}, \text{Cs}, \text{Ag}$  [31,39–43], the  ${}^2_{\infty}[(\text{UO}_2)_2\text{V}_2\text{O}_8]^{2-}$  layers are built from  $\text{UO}_7$  pentagonal bipyramids linked by  $[\text{V}_2\text{O}_8]^{6-}$  units formed by two inverse  $\text{VO}_5$  square pyramids sharing an edge. In  $A\text{UNbO}_6$ ,  $A = \text{K}, \text{Rb}$ , the  ${}^2_{\infty}[(\text{UO}_2)\text{NbO}_4]^-$  layers are built from edge sharing of two types of chains formed from edge-sharing  $\text{UO}_5$  pentagonal bipyramids and corner-shared  $\text{NbO}_5$  triangular bipyramids, respectively [44]. Astonishingly,  $\text{CsUNbO}_6$  adopts a structure derived from the carnotite as the  $A\text{UVO}_6$  compounds [45]. Surprisingly, with  $\text{Tl}$ , a tunneled structure was obtained for the compound  $\text{Tl}_{0.5}\text{UNbO}_{5.75}$  [44].

The structure-directing effect of the counteraction is also well illustrated by the alkaline metal uranyl tungstate, while  $\text{Na}, \text{K}, \text{Rb}$  occupy the interspace between layers formed by the linkage of uranyl and tungstate polyhedra [16–18], the smaller  $\text{Li}$  counteraction leads to the formation of frameworks [19].

To explain the role of the alkaline metal, we decided a systematic reinvestigation of the  $A\text{–U–Nb–O}$  systems. The purpose of the present paper is to report synthesis of  $A\text{UNbO}_6$  ( $A = \text{Li}, \text{Na}, \text{K}, \text{Cs}$ ) and  $A_{0.5}\text{UNbO}_{5.75}$  ( $A = \text{Rb}, \text{Cs}$ ) compounds and to compare their crystal structures.

## 2. Experimental

### 2.1. Crystal and powder synthesis

For each alkaline metal, powder samples were synthesized by a solid-state reaction between mixtures of  $A_2\text{CO}_3$  ( $A = \text{Li}, \text{Na}, \text{K}, \text{Rb}, \text{Cs}$ , Aldrich),  $\text{Nb}_2\text{O}_5$  (Prolabo) and  $\text{U}_3\text{O}_8$  (Prolabo) in two molar ratios: 1:1:2/3 and 1/2:1:2/3 corresponding to the hypothetical compounds  $A\text{UNbO}_6$  and  $A_{0.5}\text{UNbO}_{5.75}$ , respectively. Mixed starting materials in the appropriate stoichiometries were heated in platinum crucibles in air successively at 800 °C for 24 h and at 1000 °C for 100 h with an intermediate grinding. The achievement of the synthesis process for each sample was

controlled by X-ray powder diffraction using a Guinier-De Wolff focusing camera and  $\text{CuK}\alpha$  radiation.

For each composition, to obtain single crystals, a second batch was prepared according to the precedent process and finally melted in a platinum crucible during 48 h at 1300 °C, except for the  $\text{NaUNbO}_6$  composition for which the final temperature was 1350 °C. The melted samples were finally slowly cooled at 1 °C/min to room temperature.

### 2.2. Powder compounds characterization

For each compound, powder X-ray diffraction data used for lattice parameters refinement were recorded on a Bruker D8  $\theta/2\theta$  diffractometer, at room temperature, using Bragg–Brentano geometry, with a back-monochromatized  $\text{Cu}(K\alpha)$  radiation. The diffraction patterns were scanned over the range 5–100°(2 $\theta$ ) in steps of 0.02°(2 $\theta$ ) and a counting time of 20 s per step. The unit cell parameters were refined by a least-squares procedure from the indexed powder reflections.

The densities were measured with an automated Micromeritics Accupyc 1330 helium pycnometer using a 1-cm<sup>3</sup> cell.

To study the thermal stability of the compounds, differential thermal analyses (DTA) was performed in air with a SETARAM 92-1600 thermal analyzer in the temperature range of 20–1200 °C with heating and cooling rates of 2 °C/min, using platinum crucibles. For all compounds, no peak has been observed in this temperature range. The powder X-ray diffraction analysis of the residues after DTA measurement, confirms the only existence of the starting single phases.

### 2.3. Single crystal X-ray diffraction

Well-shaped crystals for  $\text{LiUNbO}_6$  (**1**),  $\text{Na}_{0.92}\text{Cs}_{0.08}\text{UNbO}_6$  (**7**),  $\text{KUNbO}_6$  (**3**),  $\text{Rb}_{0.5}\text{UNbO}_{5.75}$  (**5**), and  $\text{Cs}_{0.5}\text{UNbO}_{5.75}$  (**6**) were selected for structure determinations. Each single crystal was mounted on a Bruker Platform three circles X-ray diffractometer equipped with a 1K SMART CCD detector and operated at 50 kV and 40 mA. For each compound, preliminary unit cell parameters were determined from 30 frames with 20 s exposure times using SMART and the intensities of reflections for a sphere were measured with a graphite monochromated  $\text{MoK}\alpha$  radiation, using a combination of three sets of 600 frames, where each frame covered a range of 0.3° in  $\omega$  scan. Thus, a total of 1800 frames were collected with an exposure time of 50 s per frame. The intensity reduction and correction of Lorentz, polarization and background effects, were done by the program SAINTPLUS 6.02 [46]. For each single crystal data, absorption corrections based on the precise crystal morphology and indexed crystal faces were applied using the program XPREP of the SHELXTL package [47] followed by SADABS program [48]. The crystal structures were solved by a combination of direct methods and difference Fourier syntheses, and refined by full matrix least squares against  $F^2$ , using SHELXTL package of programs [47].

### 3. Results

#### 3.1. Syntheses

Pure powder samples were obtained corresponding to  $AUNbO_6$  for  $A = \text{Li}$  (**1**),  $\text{Na}$  (**2**),  $\text{K}$  (**3**) and  $\text{Cs}$  (**4**) and to  $A_{0.5}UNbO_{5.75}$ , for  $A = \text{Rb}$  (**5**) and  $\text{Cs}$  (**6**). For all compounds, cell parameters were refined from powder X-ray diffraction data, using Rietveld method and Fullprof program [49]. Using single crystal results for  $\text{LiUNbO}_6$ , the powder X-ray diffraction pattern of **1** is unambiguously indexed with a monoclinic unit cell and refined parameters  $a_1 = 10.3087(8)$ ,  $b_1 = 6.4214(6)$ ,  $c_1 = 7.6553(6)$  Å,  $\beta_1 = 101.18(1)^\circ$ . In accordance with the single crystal results, the powder X-ray diffraction data of **3**, **5** and **6** are unambiguously indexed with an orthorhombic unit cell parameters with refined parameters ( $a_3 = 10.2537(2)$ ,  $b_3 = 7.5788(1)$ ,  $c_3 = 13.3824(2)$  Å;  $a_5 = 10.4270(5)$ ,  $b_5 = 7.6585(3)$ ,  $c_5 = 13.3824(2)$  Å and  $a_6 = 13.7674(8)$ ,  $b_6 = 10.6157(6)$ ,  $c_6 = 7.6912(4)$  Å) for **3**, **5** and **6**, respectively. Indexation of powder X-ray diffraction patterns indicates a  $B$ -lattice for **6** and a  $P$ -lattice **3** and **5**. For compound **4**, both powder and single crystal X-ray diffraction data indicated that this compound adopt the layered crystal structure reported by Gasperin [45].

For  $M = \text{Li}$ ,  $\text{K}$ , single crystals of formula  $MUNbO_6$ , **1** and **3**, were obtained whatever the starting stoichiometry. For  $M = \text{Rb}$ , for the starting compositions, crystals of  $\text{Rb}_{0.5}UNbO_{5.75}$  (**5**) were grown. For  $M = \text{Cs}$ , two types of single crystals corresponding to  $\text{Cs}_{0.5}UNbO_{5.75}$  (**6**) and  $\text{CsUNbO}_6$  (**4**) were isolated from the corresponding stoichiometric starting mixtures. Except for **2**, unit cell parameters of the isolated single crystals correspond to those of the prepared powder. In fact, the single crystal obtained for the composition corresponding to **2** gave a unit cell similar to that of the  $\text{K}$ -compound **3**. An energy dispersive spectroscopy (EDS) analysis on the single crystal used for the structure determination revealed the presence, in more of the expected elements, of  $\text{Cs}$  in a small quantity from the furnace contaminated by the previous experiments using cesium carbonate. This result will be discussed in the appropriate section. For all other crystals, EDS analysis indicate only the chemical elements used at the beginning of each reaction.

In the absence of single crystal structure determination and known cell parameters for the sodium compound **2**, about 20 pattern peak positions are extracted with the *Topas P* of *BRUKER-DIFFRAC<sup>plus</sup>* software package, and used to determine cell parameters. To obtain peak positions with the maximum of precision each reflection profile was refined using the pseudo-Voigt function. The cell parameters were obtained by combination the indexing programs TREOR [50] and DICVOL [51,52], using all extracted reflections. Thus, the X-ray diagram of this phase has been indexed and refined in a monoclinic system with cell parameters and indexed reflections given in Table 1.

$\text{NaUNbO}_6$ :  $a = 13.3777(5)$  Å,  $b = 7.0010(2)$  Å,  $c = 7.9282(2)$  Å and  $\beta = 117.25(1)^\circ$ .

#### 3.2. Structure refinement and solution

Systematic absences of reflections were consistent with  $P2_1/c$  centro-symmetric space group for **1**. The measured density indicated  $Z = 4$  formula per unit cell with  $\rho_{\text{mes}} = 5.80(3)$  and  $\rho_{\text{calc}} = 5.84(2)$   $\text{g cm}^{-3}$  calculated for  $\text{LiUNbO}_6$ .

For **3**, **5** and **7**, systematic absences of reflections were consistent with  $Pnma$  centro-symmetric space group. The densities calculated for the formula  $\text{KUNbO}_6$  and  $\text{Rb}_{0.5}UNbO_{5.75}$  with  $Z = 8$  and 4 formula per unit cell, 5.91(1) and 5.57(3)  $\text{g cm}^{-3}$ , respectively, are in good agreement with the measured values,  $\rho_{\text{mes}} = 5.93(3)$  and 5.54(5)  $\text{g cm}^{-3}$ .

Finally, for **6**, the crystal structure was solved in  $Cmcm$  space group. The cell parameters are also reported in the non-conventional  $Bbmm$  space group for comparison. The measured density, 5.65(3)  $\text{g cm}^{-3}$ , is in good accordance with the calculated value considering  $Z = 4$  formula  $\text{Cs}_{0.5}UNbO_{5.75}$  per unit cell, 5.67(1)  $\text{g cm}^{-3}$ .

The structures were solved in the above centro-symmetric space groups and in the last cycles of refinement atomic coordinates and anisotropic displacement parameters were refined for all atoms, except Li in **1** for which an isotropic displacement parameter was used. For **5**, the Rb alkaline metal site is half-occupied. For **5** and **6**, oxygen sites, O(9) and O(5), respectively, are three-quarters occupied leading to acceptable displacement parameters and achieving electro-neutrality. Relevant crystallographic information is compiled in Tables 2 and 3 for  $AUNbO_6$  and  $A_{0.5}UNbO_{5.75}$  compounds, respectively. The final atomic positions with isotropic (for Li in **1**) or equivalent displacement parameters are presented in Table 4 for **1**, in Table 5 for **3**, **7** and **4**, and in Table 6 for **6**.

## 4. Description of the crystal structures

### 4.1. $LiUNbO_6$

Selected interatomic distances for  $LiUNbO_6$  with the uranyl ion angle, and bond valence sums calculated using Burns et al. data [53] for U–O bonds and Brese and O’Keeffe parameters [54] for the other bonds, are reported in Table 7.

The crystal structure of  $LiUNbO_6$  is built from an assemblage of  $NbO_6$  distorted octahedra and  $UO_7$  pentagonal bipyramids to give a two-dimensional arrangement. The only independent uranium atom is bonded to O(1) and O(2) atoms at short distances of 1.837(11) and 1.811(12) Å,

respectively, forming a nearly linear uranyl  $UO_2^{2+}$  ion,  $179.1(5)^\circ$ . The uranyl ion is further coordinated by five equatorial oxygen atoms at distances in the range 2.265(9)–2.404(11) Å to give a pentagonal bipyramidal environment. The  $UO_7$  bipyramids share the opposite O(4)–O(5) equatorial edges, creating infinite  ${}^1_\infty[UO_5]^{4-}$  chains running down [001], Fig. 1a. Such infinite chains are observed in many uranyl oxides, where the chains are connected by various ways, as for example, in the previously reported compounds  $UVO_5$  [29–31],  $USbO_5$

[55],  $UMo_2O_8$  [56],  $U_2P_2O_{10}$  [57], and in other recently studied compounds like uranyl divanadate,  $(UO_2)_2V_2O_7$  [58,59], pentahydrated uranyl orthovanadate  $(UO_2)_3(VO_4)_2 \cdot 5H_2O$  [23],  $A_6(UO_2)_5(VO_4)_2O_5$  with  $A = Na, K, Rb$  [22,24],  $K_2(UO_2)W_2O_8$  [16,17] and  $Li_2UO_2(WO_4)_2$  [19]. The topological studies of uranyl compounds [60,61] show the importance of these  ${}^1_\infty[UO_5]^{4-}$  chains in the structure of numerous uranyl compounds. The only independent niobium atom presents a very distorted octahedral environment of oxygen atoms, with four atoms at distances

Fig. 1. The layer  ${}^2_{\infty}[(\text{UO}_2)(\text{NbO})\text{O}_3]^-$  in  $\text{LiNbUO}_6$  (c) built by edge sharing between  ${}^1_{\infty}[\text{UO}_5]^{4-}$  chains of edge-shared  $\text{UO}_7$  pentagonal bipyramids (a) and  ${}^1_{\infty}[\text{NbO}_4]^{3-}$  chains of corner-shared  $\text{NbO}_5$  square pyramids (b).

from 1.951(9) to 1.988(10) Å forming a square and two axial oxygen atoms at shorter and longer distances, 1.783(11) and 2.425(12) Å, respectively; so the coordination of Nb approximates to square pyramidal. Each  $\text{NbO}_5$  square pyramid shares equatorial corners O(3) with two adjacent pyramids to form a chain  ${}^1_{\infty}[\text{NbO}_4]^{3-}$  running down [001], Fig. 1b. Thus  ${}^2_{\infty}[(\text{UO}_2)(\text{NbO})\text{O}_3]^-$  layers are formed by the association by edge sharing of these two types of chains alternating along [010], Fig. 1c. The resulting layers are of uranophane sheet anion topology [60,61], where pentagons are occupied by U and squares by Nb. Two consecutive layers at  $x \sim 0.3$  and  $\sim 0.7$  related by a center of symmetry form a double sheet, Fig. 2a. The  $\text{Li}^+$  ions are located in the available space between successive double layers and are found to be at the centers of nearly regular tetrahedra of oxygen atoms. Thus, the  $\text{LiUNbO}_6$  structure results from the stacking of neutral sandwiches of  $\{(\text{UNbO}_6)^- - (\text{Li})_2^{2+} - (\text{UNbO}_6)^-\}$ , of  $\text{Li}^{2+}$  layers between two  $\text{UNbO}_6^-$  uranyl niobate sheets, Fig. 2a. The bonds between the neutral sandwiches are very weak, they correspond to the formation of weak Nb–O bonds, with Nb–O distance of 2.425(12) Å, involving oxygen of uranyl ions and leading to a distorted octahedral environment of Nb atoms. The contribution of the O(2) atom to the valence bond sum of Nb is 0.25 v.u.

Bond valence sums calculation provides values of 5.93, 5.03 and 0.81 for U, Nb, and Li, respectively, which are consistent with formal valences  $\text{U}^{6+}$ ,  $\text{Nb}^{5+}$  and  $\text{Li}^+$ . For oxygen atoms the calculated valence bond sums ranged from 1.83 to 2.13 with an average value of 1.96, showing that the oxygen atoms are only in the  $\text{O}^{2-}$  ion oxide form.

It is interesting to compare the structure of  $\text{LiUNbO}_6$  with those of  $\text{UMO}_5$  ( $M = \text{Mo}, \text{Sb}, \text{V}, \text{Nb}$ ) compounds, which contain  $\text{U}^{4+}$  ( $M = \text{Mo}$ ) [62] or  $\text{U}^{5+}$  ( $M = \text{Sb}, \text{V}, \text{Nb}$ ) [29–31,55]. In these compounds,  $(\text{UO}_5)_{\infty}$  chains share edges with square bases of  $\text{MO}_6$  distorted octahedra resulting in layers of uranophane sheet anion topology [60,61] that are stacked by perpendicular chains containing–U–O–U–O–and–M–O–M–O–for  $M = \text{Mo}, \text{V}, \text{Nb}$ , and heterometallic–U–O–Sb–O–U–O–Sb–O–in  $\text{USbO}_5$ .

In these compounds with pillared layer structure, no uranyl group is present, the U–O bond lengths along the chains perpendicular to the layers are greater than 2.0 Å. One can imagine that  $\text{LiUNbO}_6$  structure can be deduced from  $\text{USbO}_5$  [55] (Fig. 2b), by the replacement of  $\text{U}^{5+}$  by  $\text{U}^{6+}$  leading to the formation of uranyl bonds and by the separation of two successive sheets once on two to create interspace occupied by the alkaline ions. In some cases, all the layers are separated by alkaline metals to form monolayered structures. Thus, the layered structure of the  $A\text{UNbO}_6$  ( $A = \text{K}, \text{Rb}$ ) compounds reported by Gasperin et al. [44] is obtained, in which  $A$  atoms occupy all the spaces between consecutive  ${}^2_{\infty}[(\text{UO}_2)(\text{NbO})\text{O}_3]^-$  layers, Fig. 2c. However, it is noticed that in  $\text{LiUNbO}_6$  the apical NbO bands of one layer are all oriented above the layer, while in  $A\text{UNbO}_6$  ( $A = \text{K}, \text{Rb}$ ) they alternate above and below the layer for successive chains leading to corrugated layers.

#### 4.2. $A\text{UNbO}_6$ , $A = \text{K}, (\text{Na}, \text{Cs})$

Selected interatomic distances with uranyl ion angles, and bond valence sums for **3** and **7** are reported in Table 8.

The crystal structure of  $\text{KUNbO}_6$  determined by the present study contains two independent uranium atoms, U(1) and U(2) in particular positions (4c). The local environment about each uranium is a pentagonal bipyramid, with shorter axial bonds in the range 1.788(9)–1.799(11) Å and longer equatorial bonds in the larger range 2.292(6)–2.443(9) Å, typical of  $\text{UO}_2^{2+}$  uranyl ion. The equatorial mean bond lengths of 2.357(2) and 2.365(2) Å for  $\text{U}(1)\text{O}_2^{2+}$  and  $\text{U}(2)\text{O}_2^{2+}$ , respectively, are in excellent agreement with the average bond length of 2.37 Å determined by Burns et al. [53] for uranyl ions in pentagonal bipyramidal coordination from numerous well refined structures. U(1) and U(2) alternate in  ${}^1_{\infty}[\text{UO}_5]^{4-}$  chains similar to that found in  $\text{LiUNbO}_6$  and running down [010], Fig. 3a. There is one independent niobium atom in an octahedral environment of oxygen atoms with distances in the range 1.969(7)–2.008(8) Å. Two  $\text{NbO}_6$

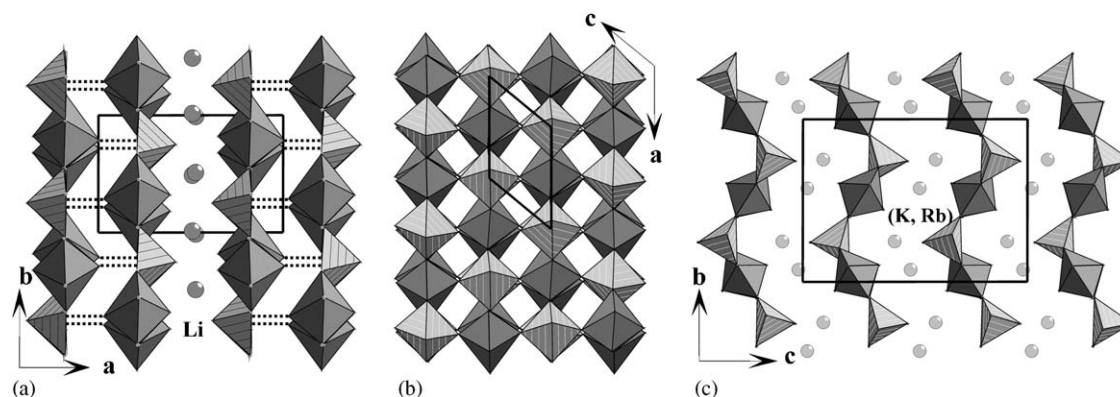

Fig. 2. Comparison of the structures of  $\text{LiNbUO}_6$  (a),  $\text{USbO}_5$  (b) and  $A\text{NbUO}_6$  ( $A = \text{K}, \text{Rb}$ ) (c), built from the same type of layers that are pillared in  $\text{USbO}_5$  (b), separated once on two by  $\text{Li}^+$  in  $\text{LiNbUO}_6$  (a) and all separated by alkaline cation  $A^+$  in  $A\text{NbUO}_6$  compounds as reported by Gasperin [42] (c) The orientation of successive  $\text{NbO}_5$  pyramids leads to planar layers in  $\text{LiNbUO}_6$  and to corrugated layers in  $A\text{NbUO}_6$  ( $A = \text{Rb}, \text{Cs}$ ).

octahedra share an O(9)–O(9) edge to form a dimeric unit, the dimeric units are further linked by corners to build a  ${}^1_{\infty}[\text{Nb}_2\text{O}_8]^{6-}$  infinite ribbon, two octahedral wide, running down [010], Fig. 3b. The ribbons can also be considered as two chains of corner-shared octahedra, similar to those found in  $\text{LiUNbO}_6$ , connected by edges. The  ${}^1_{\infty}[\text{UO}_5]^{4-}$  chains and the  ${}^1_{\infty}[\text{Nb}_2\text{O}_8]^{6-}$  ribbons are associated by edge sharing to build a three-dimensional arrangement that creates large elliptic tunnels running down [010] and occupied by K atoms, Fig. 3c. The uranyl oxygen atoms point towards the center of the tunnels that can be described as formed by trigonal prism of uranyl oxygen atoms O(2)O(1)O(4)–O(4)O(6)O(2) associated first by a O(4)O(2)O(4)O(2) lateral square face and further by the trigonal faces O(1)O(2)O(4) and O(6)O(4)O(2). The K

atoms occupy all the trigonal prisms and, to minimize the  $\text{K}^+ - \text{K}^+$  repulsion across the shared O(4)O(2)O(4)O(2) faces, they are displaced towards the O(4)O(2)O(4)O(2) lateral square face resulting in intra-dimer  $\text{K}^+ - \text{K}^+$  distance of 3.297(4) Å and an eight-fold coordination of K by oxygen atoms with K–O distances ranging from 2.644(7) to 3.165(8) Å, the oxygen O(9) and O(7) of a  $\text{Nb}_2\text{O}_8$  dimer supplementing the alkaline trigonal prism environment to form a very distorted polyhedron, Fig. 4a.

On the basis of U–O, Nb–O and K–O distances, the calculated bond valence sums are 6.06 v.u. for U(1), 6.04 v.u. for U(2), 4.95 v.u. for Nb, and 1.22 v.u. for K, these values are consistent with formal valences of  $\text{U}^{6+}$ ,  $\text{Nb}^{5+}$  and  $\text{K}^+$ . The bond valence sums for the O atoms are in the range from 1.79 to 2.15 v.u.

Fig. 3.  $\infty^1[\text{UO}_5]^{4+}$  chains of edge-shared  $\text{UO}_7$  pentagonal bipyramids (a) and  $\infty^1[\text{Nb}_2\text{O}_8]^{6-}$  infinite ribbons, two octahedra wide (b), connected through edges to form a three-dimensional arrangement creating large elliptic tunnels running down the  $[010]$  and occupied by  $\text{K}^+$  ions (c).

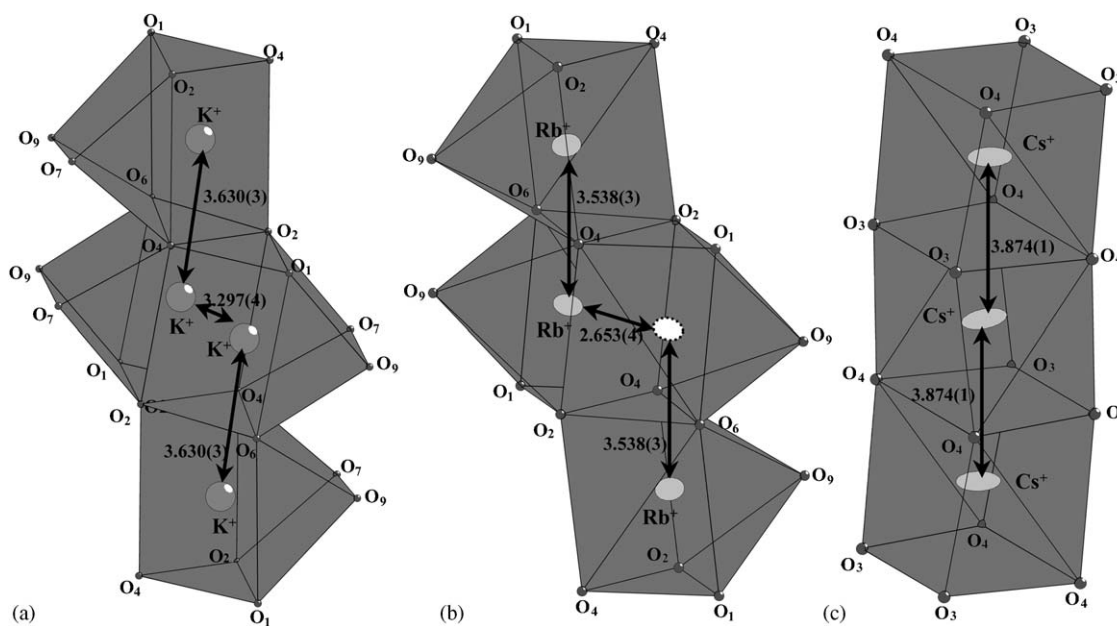

Fig. 4. In  $\text{KUNbO}_6$  and  $\text{Rb}_{0.5}\text{UNbO}_{5.75}$ , the tunnels are formed by trigonal prisms of uranyl oxygen atoms  $\text{O}(2)\text{O}(1)\text{O}(4)–\text{O}(4)\text{O}(6)\text{O}(2)$  associated first by a  $\text{O}(4)\text{O}(2)\text{O}(4)\text{O}(2)$  lateral square face and further by the trigonal faces  $\text{O}(1)\text{O}(2)\text{O}(4)$  and  $\text{O}(6)\text{O}(4)\text{O}(2)$ . The  $\text{K}$  atoms in occupy all the trigonal prisms and are displaced toward the  $\text{O}(4)\text{O}(2)\text{O}(4)\text{O}(2)$  lateral square face resulting in an eight-fold coordination of  $\text{K}$  (a). The  $\text{Rb}$  atoms occupy half the trigonal prisms and intra-tunnel disorder or intra-tunnel order (b) and inter-tunnel disorder can be imagined. In  $\text{Cs}_{0.5}\text{UNbO}_{5.75}$ , the tunnels are formed by columns of face-shared cubes of uranyl oxygen atoms  $(\text{O}(3)\text{O}(4))_4$  occupied by the  $\text{Cs}$  atoms (b).

For compound **7**, in agreement with the EDS results, the alkaline metal site was occupied both by  $\text{Na}$  and  $\text{Cs}$ , the occupation rate was refined to  $\text{Na}/\text{Cs} = 0.923(7)/0.077(7)$  leading to the crystallographic formula  $\text{Na}_{0.92}\text{Cs}_{0.08}\text{UNbO}_6$ . This mixed compound is isotopic with  $\text{KUNbO}_6$ . The  $\text{Cs}^+$  ion plays a template role, which allows the construction of the uranyl niobate framework around this large cation. In fact, the tunnels are too large to accommodate little cations such as  $\text{Na}^+$  only as shown by the too large  $\text{Na}–\text{O}$  distances leading to under-bonded ion revealed by the

valence bond sum value calculated considering  $\text{Na}^+$  only within the tunnels.

tunnels by alkaline metals. The rubidium compound is isostructural to  $\text{KUNbO}_6$ . The ionic radius of  $\text{Rb}^+$  ion does not allow the simultaneous occupation of all the (8d) sites, in fact they are half occupied. The two square face-shared trigonal prism forming the tunnels are never simultaneously occupied, so there is no more repulsion (the distance between an occupied and an empty site is

Fig. 6. Projection of the  $\text{Cs}_{0.5}\text{UNbO}_{5.75}$  crystal structure in (001) showing the occupation of the cylindrical tunnels by  $\text{Cs}^+$  ions.

2.653(4) Å and Rb occupy nearly the center of a trigonal prism with a larger Rb–O(9) distance; furthermore, the O(7) atom does not participate to the Rb coordination which can be described as a mono-capped trigonal prism, Fig. 4b. Various order types can be imagined, an intra-tunnel ordering, with Rb–Rb distances of [3.539(3)–4.143(3) Å] Fig. 5a, [4.658(4)–4.143(3)–4.658(4)–3.539(3) Å] Fig. 5b, or more probably, an intra-tunnel ordering Rb–Rb distance of 4.658(4) Å, Fig. 5c, and an inter-tunnel disorder. No supplementary reflection indicates the existence of an inter-tunnel order. For  $A = \text{Tl}$ , the isotopic compound  $\text{Tl}_{0.5}\text{UNbO}_{5.75}$  has been reported [44].

For the larger alkaline metal Cs, the polyhedral arrangement is more symmetric, Fig. 6, and tunnels with pseudo-square section are created, so the Cs atom is coordinated by eight uranyl oxygen atoms forming a slightly distorted cube. The tunnels can be described as a succession along [010] of face-shared CsO<sub>8</sub> cubes, Fig. 4c.

### 5. Discussion: the $A_{1-x}UMO_{6-x/2}$ ( $M = V, Nb$ ) compounds, layered and tunneled structures

The various uranyl vanadate and uranyl niobate compounds reported for  $x = 0$  and 0.5 are reported in Table 10. For  $M = V$ ,  $AUVO_6$  compounds exist for  $A = Na, K, Rb$  and Cs [39–43] as mineral or synthetic and adopt the carnotite-type layered structure in which  $V^{5+}$  is in a square pentagonal pyramidal coordination. Crystal structures of  $LiUVO_6$  and  $A_{0.5}UVO_{5.75}$  compounds have not been reported up to now. For  $M = Nb$ , the results are more conflicting. With  $A = Li$  and Na, previous attempts to prepare  $AUNbO_6$  compounds by solid-state reaction were unsuccessful [63]; in fact, hydrated uranyl niobates  $LiUNbO_6 \cdot 2H_2O$  and  $NaUNbO_6 \cdot H_2O$  were obtained from  $KUNbO_6$  by ion exchange, their thermal dehydration gave the anhydrous phases  $AUNbO_6$ . On the basis of unit cell parameters (Table 10) determined from X-ray powder diffraction data, compared to that of layered  $KNbUO_6$  [44], layered structures have been announced [63]. For  $LiUNbO_6$ , the layered structure of the anhydrous compound has been confirmed in the present study, but with different lattice parameters. For  $NaUNbO_6$ , a different unit cell is obtained and ab-initio crystal structure determination is planned. With  $A = K$  and Rb, layered structure has been previously reported from X-ray single crystal diffraction study [44], but the author did not report the synthesis of the corresponding powders. Our attempts

to prepare these compounds failed just as those of the monoclinic modification of  $RbUNbO_6$  [64]; on the contrary, we obtain both powder and single crystals of  $KUNbO_6$  and  $Rb_{0.5}UNbO_{5.75}$  with similar tunneled structure. Finally, with  $A = Cs$ , the existence of a layered compound  $CsUNbO_6$  with a carnotite-type uranyl-niobate layer described by Gasperin [45] has been confirmed in the present work; furthermore, a new tunneled compound  $Cs_{0.5}UNbO_{5.75}$  has been obtained. These results show the complexity and interest of the crystal chemistry of the uranyl niobates and the key role of the alkaline cation on both connectivity and dimensionality of the obtained crystal structures. While Li occupy the inter-space between layers formed by the linkage of uranyl and niobium polyhedra, the larger K, Rb and Cs countercations lead to the formation of layers or frameworks. The cases of  $Rb_{0.5}UNbO_{5.75}$  and  $Cs_{0.5}UNbO_{5.75}$  are particularly instructional, the largest Cs cation directing the building of a more symmetrical framework around it. It is also noteworthy that the presence of a small quantity of Cs leads to the formation of the tunneled structure instead of the layered one as exemplified by compound 7 and by the previously reported compound  $(Cs_{0.75}K_{0.25})U_2(Nb,Ti)O_{11}$  [65].

### 6. Conclusion

Depending on the nature of the alkaline metal, layered or tunneled uranyl niobates are prepared. Layered compounds  $AUNbO_6$  are obtained in this work for  $A = Li$  and Cs with layers of two types built from uranium pentagonal bipyramids and niobium square pyramids. For  $A = Li$ , the layers result from edge sharing of  ${}^{\infty}[UO_5]^{4-}$  chains of edge-shared  $UO_7$  polyhedra and  ${}^{\infty}[NbO_4]^{3-}$  chains of corner-shared  $NbO_5$  polyhedra. Compounds with

similar layers have been previously described for  $A = \text{K}$  and  $\text{Rb}$  [44]; we were unable to synthesize these compounds. For  $A = \text{Cs}$ , the layers are similar to those of the carnotite-type compounds  $A\text{UVO}_6$  [45]. For  $A = \text{K}$ , the structure of the  $\text{KUNbO}_6$  compound prepared in this work is built on a three-dimensional framework that results from edge sharing of  ${}^1_{\infty}[\text{UO}_5]^{4-}$  chains and  ${}^1_{\infty}[\text{Nb}_2\text{O}_8]^{6-}$  ribbons, two octahedral wide, creating large elliptic tunnels running down the [010] and occupied by  $\text{K}^+$  ions. Similar frameworks are obtained in the homeotypic compounds  $A_{0.5}\text{UNbO}_{5.75}$  for  $A = \text{Rb}$  and  $\text{Cs}$ . For  $A = \text{Rb}$ , the cationic site within the tunnels is half-occupied as in the previously reported compound  $\text{Tl}_{0.5}\text{UNbO}_{5.75}$  [44]. For  $A = \text{Cs}$ , the polyhedral framework which is built around the large alkaline metal is more symmetric and the tunnel section is a square. In these  $A_{0.5}\text{UNbO}_{5.75}$  compounds, the cation deficit is compensated by partial oxygen site vacancy.

The reasons for which Gasperin obtained layered compounds  $A\text{UNbO}_6$  for  $A = \text{K}$  and  $\text{Rb}$  are not obvious. Using the synthesis conditions of Gasperin, we obtained single crystals having the tunneled structure reported in the paper. The powder corresponding to the Gasperin compounds cannot be obtained. On the other hand, we are able to synthesize our compounds in quantity. At most, one can say that (1) the formation of the tunneled structure requires the presence of a large cation which plays a template role, (2) the layered structure is perhaps stabilized by substitution of  $\text{Nb}$  by, for example,  $\text{V}$  which supports layered structures. Further studies are needed, in particular ion exchanges and substitutions, both on the alkaline and the niobium sites, to determine the role of doping agents in the stabilization of layered or tunneled structures which would be of interest for the immobilization of  ${}^{137}\text{Cs}$ . The possibility of “pumping”  $\text{Cs}$  by uranium–niobium oxides, as already shown by Gasperin [65], is also of interest for decontamination. Measurements of conductivity properties are also planned, as a matter of fact, layered and tunneled characters of the structures are favorable to cationic mobility; moreover, the introduction of oxygen vacancies could generate oxygen mobility.
