BaSiF<sub>6</sub>

Tubular silica

Hydrothermal synthesis.

### ABSTRACT

A simple hydrothermal reaction between Ba(NO<sub>3</sub>)<sub>2</sub> and K<sub>2</sub>SiF<sub>6</sub> results in the formation of 1D rod-like BaSiF<sub>6</sub>. The BaSiF<sub>6</sub> rods can act as efficient precursors for production of tubular SiO<sub>2</sub> by hydrothermal reaction in alkaline solutions. Powder X-ray diffraction (XRD), X-ray photoelectron spectra (XPS), transmission electron microscopy (TEM), high resolution electron microscopy (HRTEM), and field emission scanning electron microscopy (FESEM) were used to characterize the phase and morphology of the final product. The experiments indicated the amount of NaOH, reaction temperature, and reaction time played important roles in the transformation process. A possible growth mechanism of tubular silica was proposed.

### 1. Introduction

Recently, much research effort has been devoted to the design and synthesis of tubular materials since the first discovery of carbon nanotubes [1]. Up to now, various tubular structures such as metals (Au [2] and Te [3]), sulfides [4], nitrides [5] and oxides (SiO<sub>2</sub> [6], ZnO [7], TiO<sub>2</sub> [8], VO<sub>x</sub> [9], and CeO<sub>2</sub> [10]) have been fabricated. Amongst the oxide systems, silica has attracted particular attention because of their potential applications as a catalyst support material [11], as a core material for biosensors and biomarkers [12], as storage/delivery containers for biochemical substances [13] and in optoelectronic nanodevice design [14,15]. Two synthetic approaches to silica nanotubes have been reported, namely, template approach [16] and direct chemical/physical routes [17,18]. As a representative synthetic method, several templates have been developed for the synthesis of tubular SiO<sub>2</sub>, such as surfactant [19], organogelators [20,21], biological substrates [22], organic ammonium carboxylate crystals [23], nanoporous membrane materials [24,25], carbon nanotubes [26,27], fiber-like crystals of [Pt(NH<sub>3</sub>)<sub>4</sub>](HCO<sub>3</sub>)<sub>2</sub> [28], ZnS [29], V<sub>3</sub>O<sub>7</sub>·H<sub>2</sub>O [30] and so on. However to the best of our knowledge, most reported templates for the preparation of tubular SiO<sub>2</sub> only act as a physical template to control the size

and morphology of the final product and contain nothing of the chemical composition of the desired product. Herein, we report on the synthesis of the tubular SiO<sub>2</sub> in alkaline solutions by employing rod-like BaSiF<sub>6</sub> as both the physical and chemical templates. No other additive was used in the current synthesis. The advantage of using such physical/chemical template is that the final removal of the template is not required since the template has been sacrificed. Another benefit is the ease control of the composition of the final material.

### 2. Experimental details

#### 2.1. Synthesis of BaSiF<sub>6</sub> precursor

All chemical reagents used in this study were of analytical grade. Ba(NO<sub>3</sub>)<sub>2</sub> (0.1 mol/L, 10 mL) and K<sub>2</sub>SiF<sub>6</sub> (0.1 mol/L, 10 mL) were mixed and stirred for 10 min. Then the mixture solution was transferred into a 30 mL stainless Teflon-lined autoclave and heated at 120 °C for 6 h. The powder samples obtained were centrifuged, washed with distilled water, and dried at 60 °C.

#### 2.2. Synthesis of tubular SiO<sub>2</sub>

The BaSiF<sub>6</sub> precursor (0.54 mmol) was dispersed into distilled water (25 mL). After the addition of NaOH (1.80 mmol), and stirred for 10 min, the mixture was transferred into a 30 mL stainless

Teflon-lined autoclave and heated at 120 °C for 6 h. The samples were collected, washed several times with distilled water, and dried at 60 °C for 4 h. A mixture of BaF<sub>2</sub> and SiO<sub>2</sub> was obtained. To obtain pure SiO<sub>2</sub>, an acid treatment was employed to remove BaF<sub>2</sub>. The mixture of BaF<sub>2</sub> and SiO<sub>2</sub> was added directly into 1.5 mol/L HNO<sub>3</sub> solution, and then were stirred for about 3 h. The solid sample obtained was washed several times with water, and dried at 60 °C for 4 h.

### 2.3. Characterizations

The crystalline phases of the products were analyzed by X-ray diffraction (XRD) on a Shimadzu XRD-6000 powder X-ray diffractometer (CuK $\alpha$  radiation  $\lambda = 1.5418 \text{ \AA}$ ) at a scanning rate of  $0.05^\circ \text{ s}^{-1}$  in the  $2\theta$  range 10–70°. The X-ray photoelectron spectra (XPS) were recorded on an ESCALAB MK II X-ray photoelectron spectrometer, using Mg K-X-ray as the excitation source. The sizes and morphologies of the products were studied by field emission scanning electron microscopy (FESEM, HITACHI-S4800), transmission electron microscopy (TEM, TECNAI-12), and high resolution electron microscopy (HRTEM, JEM-2010). X-ray fluorescence (XRF) analysis was performed on an ARL-9800 spectrometer.

## 3. Results and discussion

### 3.1. Synthesis and characterizations

The direct reaction between Ba(NO<sub>3</sub>)<sub>2</sub> and K<sub>2</sub>SiF<sub>6</sub> readily generates rod-like BaSiF<sub>6</sub> with a high yield. The XRD pattern of the precursor BaSiF<sub>6</sub> is shown in Fig. 1a. All peaks can be indexed to a pure rhombohedral phase (space group:  $R\bar{3}m$ , with lattice constant  $a = 7.198 \text{ \AA}$ ,  $c = 7.020 \text{ \AA}$ ; JCPDS 78-0031). No other impurity peaks are detected in the XRD pattern. Fig. 1b shows a typical SEM image of the product, from which many rods with lengths up to several micrometers and diameters around 300–500 nm can be clearly found.

It was expected that the rod-like BaSiF<sub>6</sub> could act as the precursor and/or template to generate the 1D nano/microstructures of Ba- or Si-containing material. Because BaSiF<sub>6</sub> is unstable in alkaline solutions, the precursor can be treated with basic solution to obtain pure SiO<sub>2</sub>. When BaSiF<sub>6</sub> was reacted with ca. 3 molar equivalence of NaOH via a simple hydrothermal procedure, and then followed by the removal of the produced BaF<sub>2</sub> through acid treatment, the pure SiO<sub>2</sub> tubes were obtained. Fig. 2a shows the XRD patterns of the products prepared by the hydrothermal process before and after the acid treatment, respectively. Before washing with acid, it is found that the

product can be indexed to a cubic  $\text{BaF}_2$  phase (space group:  $Fm\bar{3}m$ ), which is consistent with the values in the standard cards (JCPDS Card no. 04-0452). But after the acid treatment, only a broad peak at  $2\theta = 20\text{--}30^\circ$  was found in the XRD pattern, which indicated the amorphous nature of the product. The above experimental results imply that the product before washing is the mixture of  $\text{BaF}_2$  and the amorphous  $\text{SiO}_2$ . Since the diffraction peaks of  $\text{BaF}_2$  in the mixed product are very strong, the halo peak of amorphous  $\text{SiO}_2$  could not be seen in the diffraction pattern of the mixed product.

Fig. 2b shows the typical SEM images of the mixture product before treating with acid. There are many irregular particles or aggregates along with  $\text{SiO}_2$  tubes. The EDS of these irregular particles confirmed that main chemical composition is  $\text{BaF}_2$  (inset, Fig. 2b). The HRTEM image of a region of an irregular particle shows it is structurally uniform with interplanar spacing of about 0.36 nm, which corresponds to the (111) lattice spacing of  $\text{BaF}_2$  (Fig. 2c). Therefore, the identity of these irregular particles was demonstrated to be  $\text{BaF}_2$  by HRTEM and EDS. The images of the products after treating with acid were shown in Figs. 2d–g. The flower-like  $\text{SiO}_2$  microstructures consisted of  $\text{SiO}_2$  tubes could be clearly found from the images in Figs. 2d and e. A tip of a cracked  $\text{SiO}_2$  tube clearly shows a hollow interior of tubular structure with diameters in the range of 300–400 nm, and shell thickness less than 60 nm (Fig. 2f). These are further confirmed by the HRTEM image of a single  $\text{SiO}_2$  tube (Fig. 2g). No lattice fringe could be

observed for the tubular  $\text{SiO}_2$ , indicating it is in the amorphous state. The corresponding selected-area electron diffraction (SAED) pattern (inset, Fig. 2g) shows only diffuse rings without diffraction spots, which further confirm its amorphous nature. The corresponding elemental composition is confirmed by EDS (inset, Fig. 2d) to be Si and O with an approximate atomic ratio of 1:2 (the Cu signal comes from the copper grids.), indicating that these tubes are amorphous  $\text{SiO}_2$ . No obvious peak of other element such as Ba is detected. XRF data of the product indicated that only 0.3 at% Ba existed, which demonstrated that nearly all of the  $\text{BaF}_2$  produced along with  $\text{SiO}_2$  was washed away by treating with  $\text{HNO}_3$  for 3 h. The surface composition of the amorphous  $\text{SiO}_2$  was further probed by XPS (Fig. 2h). The relatively strong peaks at 154.5, 103.0, and 532.5 eV can be attributed to the bonding energies of  $\text{Si}_{2s}$ ,  $\text{Si}_{2p}$ , and  $\text{O}_{1s}$ , respectively. These results are in agreement with those reported [15,31]. No obvious peaks for Ba or F were observed besides C peaks from the XPS chamber.

The above observations showed that the rod-like  $\text{BaSiF}_6$  could be transformed into a mixture of  $\text{BaF}_2$  and  $\text{SiO}_2$ . After treating with acid, tubular  $\text{SiO}_2$  was prepared. XRD and TEM were carried out on the products isolated at different reaction stages to investigate the factors involved in the transformation process

**Fig. 3.** (a) TEM images of the products correspond to reaction stages at 2.0 h (inset, EDS) and (b) XRD patterns of the products obtained at reaction stages of 0.5, 1.0, 2.0, 6.0, 12.0, and 24.0 h, respectively.

**Fig. 4.** (a and b) SEM images of the product obtained with 2.3 mmol NaOH at  $120^\circ\text{C}$  for 6 h after washing with acid.

and the formation of the tubular SiO<sub>2</sub>. When the reaction time was shortened to 0.5 h, only random rods with a diameter around 300–500 nm were observed. The X-ray diffraction pattern of the product showed that it was pure BaSiF<sub>6</sub> with the rhombohedral structure (Fig. 3b). Increasing reaction time up to 1 h, the rods and a small quantity of tubes coexisted. The X-ray diffraction pattern of the product is mainly the rhombohedral BaSiF<sub>6</sub> (Fig. 3b). When the reaction time reaches at 2.0 h, the images in Fig. 3a showed that the partially filled rods or partial tubes were found. It appears that the tubular structures were formed from the erosion of the template starting at the tips of the rod. EDS (inset, Fig. 3a) of the partial tube shows the Ba, Si, F, and O elements coexisted, and the amount of Si is much more than that of Ba. The X-ray diffraction pattern of the product obtained at this stage showed the mixed phases of the cubic BaF<sub>2</sub> and BaSiF<sub>6</sub>. When the reaction time was further prolonged to 6 h (Fig. 2b), the mixed morphologies of tubes and irregular particles coexisted. The X-ray diffraction pattern of the product showed that the only cubic BaF<sub>2</sub> existed, indicating that BaSiF<sub>6</sub> was completely transformed

into BaF<sub>2</sub> and SiO<sub>2</sub> (Fig. 2a). Because SiO<sub>2</sub> is amorphous in nature, only those diffraction peaks of BaF<sub>2</sub> were observed. When the reaction was further prolonged (12, 24 h), the product still preserved the tubular morphology. It can be deduced that the formation of tubular SiO<sub>2</sub> involves three steps. First, the precursors BaSiF<sub>6</sub> nanorods formed. Second, the precursor is reacted with NaOH to yield a mixture of SiO<sub>2</sub> and BaF<sub>2</sub>. Finally, BaF<sub>2</sub> is removed by acid treatment, which results in the final hollow morphology.

The following reactions occur in the formation of tubular SiO<sub>2</sub>:

It has been found that the amount of alkaline have great influence on the products. When the amount of NaOH was less than 1.5 mmol, the BaSiF<sub>6</sub> rods did not completely transform into the mixture of BaF<sub>2</sub> and SiO<sub>2</sub>. When the amount of NaOH was increased to 1.8 mmol, a mixture of BaF<sub>2</sub> and SiO<sub>2</sub> was produced, and the tubular SiO<sub>2</sub> was obtained after acid washing. Further increasing the amount of NaOH to 2.3 mmol, the SiO<sub>2</sub> tubes with the diameter of 50 nm were produced after washing with acid (Fig. 4a). It should be noted that the size of this tubular product is much smaller than that of the precursor BaSiF<sub>6</sub>. Only irregular small sphere were obtained with 5 mmol NaOH.

The reaction temperature was also found to affect the transformation. At a low temperature such as 80 °C, the product was still BaSiF<sub>6</sub> rods. When temperature was raised to 120 °C, SiO<sub>2</sub> tubes were produced after washing with acid (Figs. 2e–h). Further increasing the temperature to 160 °C, the bamboo-like tubes of SiO<sub>2</sub> were obtained after washing the mixture (Figs. 5a and b). When the temperature was further raised to 180 °C, SiO<sub>2</sub> with the long bamboo-like tubes were still kept after washing the mixture with acid.

### 3.2. Growth mechanism

On the basis of all the above observations, a template-based growth mechanism of the straight silica tube is proposed. The above findings suggest that the three-stage processes are responsible for the formation of the tubular silica. The possible formation mechanism of SiO<sub>2</sub> was illustrated in Scheme 1. BaSiF<sub>6</sub> rods were formed first, which might be due to the anisotropical nature of crystal structure and intrinsic growth characteristics. The TEM image of the product obtained after reaction for 2 h shown in Fig. 3a clearly suggest that the erosion started on both ends. Therefore it is reasonable to assume that the reactivity rates of the different crystalline planes were significantly varied due to the different surface energies when BaSiF<sub>6</sub> was treated with NaOH. Two ends of BaSiF<sub>6</sub> rod reacted with NaOH much faster than the side surfaces. Therefore the erosion of the BaSiF<sub>6</sub> first occurred on the two tips, yielding the primary SiO<sub>2</sub> and BaF<sub>2</sub> particles. At the same time, these produced SiO<sub>2</sub> particles could coat on the exterior surface of BaSiF<sub>6</sub> while the produced BaF<sub>2</sub> remained in the hole or the solution. With the increasing of the

Fig. 5. TEM images of the products obtained at different temperature (a and b) 160 °C, 6 h, after washing.

Scheme 1. Schematic illustration of the tubular silica formation.

reaction time, the interior was gradually hollow and the silica sheath was developed. When the  $\text{BaSiF}_6$  was completely consumed, the mixture of  $\text{SiO}_2$  tubes and  $\text{BaF}_2$  particles were formed. The final removal of  $\text{BaF}_2$  led to the pure tubular  $\text{SiO}_2$ . Therefore, in this formation process of silica tubes,  $\text{BaSiF}_6$  rods both served as the precursor and the template. The different reactivity of crystalline planes of  $\text{BaSiF}_6$  rods with  $\text{NaOH}$  was assumed to be essential for the formation of silica tubes. The optimal reaction condition for silica tubes was the addition of 1.8 mmol  $\text{NaOH}$  with respect to 0.54 mmol  $\text{BaSiF}_6$ .

With the excess of  $\text{NaOH}$  (e.g. 2.3 mmol  $\text{NaOH}$ ), part of the  $\text{NaOH}$  would react with the ends of  $\text{BaSiF}_6$  first, the remaining  $\text{NaOH}$  would also react with the lateral surfaces of  $\text{BaSiF}_6$ . When the erosion on the different directions occur at comparable rate, which lead to the  $\text{SiO}_2$  tubes with smaller diameter. With much more  $\text{NaOH}$  was used, (i.e. 5 mmol  $\text{NaOH}$ ), the erosions on both ends and the lateral surfaces are very fast, which would destroy the template, leading to the formation of irregular particles.

#### 4. Conclusions

In summary, we have successfully fabricated tubular  $\text{SiO}_2$  and rod-like  $\text{BaF}_2$  by using  $\text{BaSiF}_6$  nanorods as precursors. The hydrothermal treatment of  $\text{BaSiF}_6$  with a certain amount of  $\text{NaOH}$  at a mild temperature (120 °C) produces  $\text{SiO}_2$  tubes. The reaction parameters such as reaction time, temperature, and the amount of  $\text{NaOH}$  were studied to investigate the factors involved in the solid–liquid interface reactions of  $\text{BaSiF}_6$  to  $\text{SiO}_2$ .  $\text{BaSiF}_6$  nanorods not only act as the precursor but also serve as chemical/physical templates, which lead to the formation of  $\text{SiO}_2$  tubes. This method may be extended to the preparation of other oxides.
