#### Abstract

The influence of aryl ring substituents X ( F , $\mathrm{OMe}, \mathrm{NMe}_{2}, \mathrm{NH}_{2}, \mathrm{OH}$ and $\mathrm{O}^{-}$) on the physical and electronic structure of the ortho-carborane cage in a series of $C, C^{\prime}$-diaryl-ortho-carboranes, $1-\left(4-\mathrm{XC}_{6} \mathrm{H}_{4}\right)$-2-Ph-1,2$\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{10}$ has been investigated by crystallographic, spectroscopic [nuclear magnetic resonance (NMR), UV-vis], electrochemical and computational methods. The cage C1C2 bond lengths in this carborane series show small variations with the electron-donating strength of the substituent $X$, but there is no evidence of a fully evolved quinoid form within the aryl substituents in the ground state. In the ${ }^{11} \mathrm{~B}$ and ${ }^{13} \mathrm{C}$ NMR spectra, the 'antipodal' shift at B12, and the C 1 shift correlates with the Hammett $\sigma_{\mathrm{p}}$ value of the substituent X . The UV-visible absorption spectra of the cluster compounds show marked differences when compared with the spectra of the analogous substituted benzenes. These spectroscopic differences are attributed to variation in contributions from the cage orbitals to

the unoccupied/virtual orbitals involved in the transitions responsible for the observed absorption bands. Electrochemical studies (cyclic and square-wave voltammetry) carried out on the diarylcarborane series reveal that oneelectron reduction takes place at the cage in every case with the voltage required for reduction of the cage influenced by the electron-donating strength of the substituent $X$, affording a series of carborane radicals with formal $[2 n+3]$ electron counts.

## Introduction

The chemistry of carborane cluster compounds has been extensively investigated over many years, and yet exploration of the synthetic, structural and electronic properties of these compounds continues to provide new insights and opportunities for further development. For example, it has long been known that despite their remarkable thermal and oxidative stability, the closo-icosahedral carboranes $\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{12}$ (most notably the 1,2-ortho isomers) are susceptible to attack by Lewis bases which remove BH units [15]. The nido-icosahedral fragment dianions $\left[\mathrm{C}_{2} \mathrm{~B}_{9} \mathrm{H}_{11}\right]^{2-}$ that result from these "decapitation" reactions feature pentagonal open faces, which can coordinate to metal centres and regenerate 12 -vertex metallacarbaborane deltahedra, which have fascinating analogies with both borane clusters and half-sandwich metal complexes [6-13].

The 12-vertex closo-ortho-carborane $\mathrm{C}_{2} \mathrm{~B}_{10}$ cage is also remarkably structurally flexible in its own right. The cage $\mathrm{C} 1-\mathrm{C} 2$ bond is sensitive to the nature of the groups bonded to the carbon centres and can be elongated by the
attachment of $\pi$-donor substituents to one or both of the cage carbon atoms [14-21]. In extreme cases, the cage acquires a tetragonal open face. For example, our work on substituted derivatives of phenyl-ortho-carborane, PhCbX (where $\mathrm{PhCb}=2-\mathrm{Ph}-1,2-\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{10}$ and $\mathrm{X}=\mathrm{H}, \mathrm{F}, \mathrm{NH}_{2}, \mathrm{NH}^{-}$, $\mathrm{OH}, \mathrm{O}^{-}$, bonded at cage carbon C 1 ) has shown that the cage $\mathrm{C}(1)-\mathrm{C}(2)$ distance increases in relation to the $\pi$-donor properties of the substituent, from $1.649(2) \AA(\mathrm{X}=\mathrm{H})$ to 2.001 (3) $\AA\left(\mathrm{X}=\mathrm{O}^{-}\right)$[22]. Structural changes of this magnitude and precision make the ortho-carborane residue a very sensitive probe of the $\pi$-donor properties of substituents.

It has long been known that two-electron reduction of icosahedral carboranes generates nido-dianions $\left[\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{12}\right]^{2-}$ [23, 24], which can be used as precursors to 13 -vertex metallacarbaboranes [25-29], with electrochemical studies of diphenyl-ortho-carborane $\mathrm{PhCbPh}(\mathbf{1})$ in acetonitrile or DMSO revealing two sequential quasi-reversible 1e reduction processes [30, 31]. Based on computational (B3LYP/6$31 \mathrm{G}^{*}$ ) studies, the geometry of the thermodynamically stable radical anion [1] ${ }^{-}$is thought to contain a long cage $\mathrm{C} 1-\mathrm{C} 2$ bond ( $2.38 \AA$ ) arising from the contribution of the additional electron to the cluster skeletal electron count [32].

We were interested in further exploring the influence of $\pi$-donor substituent effects on the physical and electronic structure of the closo-ortho-carborane cage. To this end, a series of ortho-carborane derivatives $\mathrm{PhCbC}_{6} \mathrm{H}_{4} \mathrm{X}$, containing a para-located ring substituent $\mathrm{X}=\mathrm{H}, \mathrm{F}, \mathrm{OMe}, \mathrm{NMe}_{2}$, $\mathrm{NH}_{2}$ and OH , were prepared and structurally characterised. The phenyl group at the carbon centre C 2 helps resolve possible $\mathrm{CH} / \mathrm{BH}$ disorder problems [22, 33, 34-40] and provides an internal structural and spectroscopic reference. Electrochemical measurements have been used to demonstrate that $[2 n+3]$ cluster radical anions can be generated throughout the series. In this contribution, we report structural, spectroscopic, electrochemical and computational work that reveals a degree of interaction between the carborane cage and the remote substituent, X , mediated by the intervening phenylene ring.

## Results and discussion

The parent diphenyl-ortho-carborane $\mathbf{1}$ and the $C, C^{\prime}$-diaryl-ortho-carboranes, $\mathrm{PhCbC}_{6} \mathrm{H}_{4} \mathrm{X}\left[\mathrm{X}=\mathrm{F}(\mathbf{2})\right.$, OMe (3), $\mathrm{NMe}_{2}$
(4), $\mathrm{NH}_{2}$ (5)] were prepared from reactions of the appropriate diarylethynes with decaborane (Scheme 1) [41-43]. The hydroxy derivative $\mathrm{PhCbC}_{6} \mathrm{H}_{4} \mathrm{OH} 6$ was obtained by demethylation of 3 . The sodium salt Na $\left[\mathrm{PhCbC}_{6} \mathrm{H}_{4} \mathrm{O}\right] 7$ was formed as yellow crystals from 6 and NaOH in acetonitrile.

Structural aspects
The derivatives $\mathrm{PhCbC}_{6} \mathrm{H}_{4} \mathrm{X}$ 1-6 were structurally characterised by single crystal X-ray studies, and relevant molecular parameters are listed in Table 1. The molecular geometries of 2-6 resemble that of diphenyl-ortho-carborane PhCbPh 1 reported earlier at room temperature [33] and re-determined in this work at low temperature for consistency. It is remarkable that the structures of $\mathbf{1}$ and all its derivatives contain more than one independent molecule, viz. two in 1, 2, $\mathbf{4}$ and 5, four in $\mathbf{3}$ and six in 6, the asymmetric unit of the latter also containing a half molecule of hexane, which is located at an inversion centre and partially disordered. Generally, only about $8 \%$ of molecular crystals have $Z^{\prime}>1$ [44], although the proportion is much higher for certain chemical classes, notably monoalcohols (cf. 6) [45, 46]. Persistence of $Z^{\prime}>1$ in the present case can be attributed to the shape of the diphenylcarborane moiety, which is awkward for packing yet has some conformational flexibility brought about by rotation of the phenyl groups.

In each independent molecule of 2, the p-fluorine substituent is disordered over both phenyl rings (Fig. 1). The occupancies of these positions, $F(1)$ and $F(2)$, in molecule A were refined to $93.3(3)$ and $6.7(3) \%$, in molecule B to 61.8(3) and $38.2(3) \%$.

In 3, the methoxy groups are almost coplanar with the phenyl rings to which they are attached; the torsion angle C (15) $-\mathrm{C}(16)-\mathrm{O}-\mathrm{C}(\mathrm{Me})$ being $-0.5(2), 6.0(2), 6.6(2)$ and $-5.6(2)^{\circ}$ in molecules $\mathrm{A}, \mathrm{B}, \mathrm{C}$ and D , respectively. In 4, the amino group is planar, the sum of $\mathrm{C}-\mathrm{N}-\mathrm{C}$ angles being $359.8(2)^{\circ}$ in molecule A and 359.0(4) ${ }^{\circ}$ in B . The dihedral angle between the $\mathrm{C}(19) \mathrm{N}(1) \mathrm{C}(20)$ [ $\mathrm{NMe}_{2}$ ] plane and the benzene ring is $6.1^{\circ}(\mathrm{A})$ and $10.4^{\circ}(\mathrm{B})$. In 5, the amino group is less planar than in $\mathbf{4}$, the sum of bond angles at N (1) being $349(3)^{\circ}$ in both molecules. Thus, the $\mathrm{NH}_{2}$ plane makes a dihedral angle of $26^{\circ}$ (A) or $34^{\circ}$ (B) with the benzene ring, whilst the $\mathrm{p} \pi$ orbital of $\mathrm{C}(16)$ and the lone

$\theta$ is the average difference between $90^{\circ}$ and the moduli of $\mathrm{C}_{\text {cage }}-\mathrm{C}_{\text {cage }}-\mathrm{C}_{\mathrm{Ph}}-\mathrm{C}_{\mathrm{Ph}}$ torsion angles, i.e. $\mathrm{C}(2)-\mathrm{C}(1)-\mathrm{C}(13)-\mathrm{C}(14)$ and $\mathrm{C}(2)-\mathrm{C}(1)-\mathrm{C}(13)-$ $\mathrm{C}(18)$ for $\theta_{1}, \mathrm{C}(1)-\mathrm{C}(2)-\mathrm{C}(21)-\mathrm{C}(22)$ and $\mathrm{C}(1)-\mathrm{C}(2)-\mathrm{C}(21)-\mathrm{C}(26)$ for $\theta_{2}$
${ }^{\text {a }}$ Room temperature [9]
${ }^{\mathrm{b}}$ Major disordered position
${ }^{\text {c }}$ Average of the two chemically equivalent bonds
electron pair of $\mathrm{N}(1)$ are eclipsed in molecule A and twisted by approximately $7^{\circ}$ in B. Surprisingly, there is no strong $\mathrm{N}-\mathrm{H} \ldots \mathrm{N}$ hydrogen bonding in 5 . The $\mathrm{NH}_{2}$ group of molecule $B$ has one $H$ atom pointing toward the $N(1)-C$ (16) bond rather than the $N(1)$ lone pair of molecule $A$ and another toward the $\mathrm{C}(13)-\mathrm{C}(14)$ bond of its equivalent by the transformation (i) $x-1 / 2, y, 3 / 2-z$ (Fig. 2). For the idealised $\mathrm{N}-\mathrm{H}$ bond lengths of $1.01 \AA$, the calculated distances $\mathrm{H}(2 \mathrm{~B}) \ldots \mathrm{N}(1 \mathrm{~A}) 2.48, \mathrm{H}(2 \mathrm{~B}) \ldots \mathrm{C}(16 \mathrm{~A}) 2.61, \mathrm{H}\left(1 \mathrm{~B}^{\prime}\right)$ $\ldots \mathrm{C}(13 \mathrm{~A}) 2.68$ and $\mathrm{H}\left(1 \mathrm{~B}^{\prime}\right) \ldots \mathrm{C}(14 \mathrm{~A}) 2.75 \AA$ are somewhat shorter than the sums of van der Waals radii, H...N 2.74 and H...C $2.88 \AA$. The amino hydrogens of molecule A form only $\mathrm{H} . . . \mathrm{H}$ contacts with carborane hydrogens and those not significantly shorter $(2.20-2.26 \AA)$ than twice the van der Waals radius of H ( $2.2 \AA$ ).

Fig. 1 The molecular structure of $\mathbf{2}$ (unique molecule A , thermal ellipsoids are drawn at the $50 \%$ probability level, disorder is omitted) showing the atomic numbering scheme used for compounds $\mathbf{1}$ to $\mathbf{6}$

The molecules of $\mathbf{6}$ are hydrogen-bonded into two nonequivalent centrosymmetric hexamers, viz. $A B C A^{i} B^{i} C^{i}$ and $D_{E F D}{ }^{\mathrm{ii}} E^{\mathrm{ii}} \mathrm{F}^{\mathrm{ii}}$, where symmetry operations are (i) $1-\mathrm{x},-\mathrm{y}$, $-z$ and (ii) $-x, 1-y,-z$. In the $A B C A^{i} B^{i} C^{i}$ cycle, all hydroxyl hydrogens are disordered so that hydrogen bonds can run along the ring in either direction with equal

Fig. 2 Intermolecular interactions in the crystal of 5

Fig. 3 (a) A hydrogen-bonded hexamer in the crystal of $\mathbf{6}$, (b) the pattern of disorder in the symmetrically non-equivalent hexamer (see text for the symmetry notation)

probability, whereas in the latter hexamer, the hydroxyl H atoms are ordered and the hydrogen bonds are donated in the succession $\mathrm{F} \rightarrow \mathrm{E} \rightarrow \mathrm{D} \rightarrow \mathrm{F}^{\mathrm{ii}}$, etc. (Fig. 3).

Throughout the series 2-6, both phenyl rings are orientated roughly perpendicular to the C (phenylene)- $\mathrm{C}(1)-\mathrm{C}(2)-\mathrm{C}$ (phenyl) plane, slightly rotated in the same sense (propellerlike conformation). It is helpful to the discussion to define $\theta$ as the average difference between $90^{\circ}$ and the moduli of $\mathrm{C}_{\text {cage }}-\mathrm{C}_{\text {cage }}-\mathrm{C}_{\mathrm{Ph}}-\mathrm{C}_{\mathrm{Ph}}$ torsion angles, i.e. $\mathrm{C}(2)-\mathrm{C}(1)-\mathrm{C}(13)-$ $\mathrm{C}(14)$ and $\mathrm{C}(2)-\mathrm{C}(1)-\mathrm{C}(13)-\mathrm{C}(18)$ for $\theta_{1}, \mathrm{C}(1)-\mathrm{C}(2)-\mathrm{C}(21)-$ $\mathrm{C}(22)$ and $\mathrm{C}(1)-\mathrm{C}(2)-\mathrm{C}(21)-\mathrm{C}(26)$ for $\theta_{2}$ [33]. The range of angles $\theta$ is rather small, and generally less than $15^{\circ}$, save for some members of the hydrogen-bonded networks of $\mathbf{6}$. Nevertheless, the cage $\mathrm{C}(1)-\mathrm{C}(2)$ bond is sensitive to aryl group orientations [47, 48-51], and the $\mathrm{C}(1)-\mathrm{C}(2)$ bond length is generally longest when both aryl groups are orientated perpendicular to the $\mathrm{C} 1-\mathrm{C} 2$ vector $\left(\theta=0^{\circ}\right.$, Table 1) and thereby maximising the interaction between the aryl $\pi$-system and the tangential cage carbon p-orbital [33, 47].

A more significant though still modest variation in the C (1)-C(2) bond length is observed as a function of the electronic character of the substituent X (Table 2). For example, the length in the parent compound $\mathbf{1}$ [1.726(2) $\AA$ ] is shorter than in the $\mathrm{NMe}_{2}$ derivative 4 [1.744(3), 1.752 (3) $\AA]$. The less strongly $\pi$-donating groups have more limited influence on the structure of the cage (Table 1), and in any event, the structural variations in response to the substituent are small compared to the changes in $\mathrm{C}(1)-\mathrm{C}(2)$ bond distances observed when the substituent X is directly bonded to the cage carbon $C(1)$. The $C(1)-C(13)$ and $C(2)-$ $\mathrm{C}(21)$ bond lengths in compounds $\mathbf{1 - 6}$ are largely insensitive to both the orientation of the phenyl groups and the substituent, being approximately $1.50 \AA$ in each case.

Very good agreements between the MP2/6-31G* optimised geometry and crystallographically determined structures of $\mathbf{1}$ have been noted elsewhere [47]. The MP2optimised geometries of 2-6 reveal the same trends in the cage $\mathrm{C} 1-\mathrm{C} 2$ bond lengths as observed crystallographically, i.e. the cage $\mathrm{C} 1-\mathrm{C} 2$ bond length increases with increasing electron-donating effect of X . The optimised geometry of the salt $\left[\mathrm{PhCbC}_{6} \mathrm{H}_{4} \mathrm{O}\right]^{-} \mathrm{Na}^{+} 7$ contains a $\mathrm{C} 1-\mathrm{C} 2$ bond length of $1.732 \AA$, which is approximately $0.02 \AA$ longer than those of MP2-optimised geometries of $1-6$ but much shorter than the C1-C2 bond length of $1.913 \AA$ in the MP2optimised geometry of $[\mathrm{PhCbO}]^{-} \mathrm{Na}^{+}$reported previously [22]. There is no significant quinonoidal character in the substituted ring systems in either the experimental or computational models, and in general, the bond lengths within the $\mathrm{C}(13)-\mathrm{C}(18)$ ring are comparable with those of the analogous substituted benzenes determined experimentally $[52,53]$ or by computation at the MP2/6-31G* level of theory.

## Spectroscopic aspects

## NMR spectroscopy

Within the $\mathrm{PhCbC}_{6} \mathrm{H}_{4} \mathrm{X}$ series, the increasing electrondonating effect of X causes a relative decrease in the shielding of the C 1 nuclei (Table 3) [54]. In the ${ }^{11} \mathrm{~B}$ NMR data for the series, the boron atom B 12 antipodal to C 1 is most influenced, becoming more shielded when $\mathrm{X}=\mathrm{NH}_{2}$ and $\mathrm{NMe}_{2}$. These variations in the B12 chemical shift are examples of the 'antipodal' effect [55] where the substituent at one vertex atom of a cage has a remarkable influence on the chemical shift of the vertex atom directly opposite. In contrast, the chemical shifts of C 2 and B 9 are relatively insensitive to the nature of X .

Calculated boron and carbon NMR shifts at the B3LYP/ $6-311 \mathrm{G}^{*}$ level of theory on these MP2-optimised systems also show the same trends as the observed chemical shifts where X influences the frequency of the C 1 and B 12 resonances but leaves C 2 and B 9 shifts largely unaffected. Calculated NMR values generated from the optimised geometry of the salt $\mathrm{Na}^{+}\left[\mathrm{PhCbC}_{6} \mathrm{H}_{4} \mathrm{O}\right]^{-} 7$ gave very good agreement with observed data for the sodium salt. An approximately linear relationship exists between the Hammett $\sigma_{\mathrm{p}}$ values of the substituents and both the ${ }^{13} \mathrm{C}$ chemical shifts of C 1 and the ${ }^{11} \mathrm{~B}$ NMR chemical shift of B12. This observation lends additional support to the idea that the variation in the observed chemical shifts of these nuclei is attributable to the electronic character of the substituent [56].

## Electronic structure calculations

Electronic structure calculations were carried out on the MP2-optimised geometries of $\mathrm{PhCbC}_{6} \mathrm{H}_{4} \mathrm{X} \mathbf{1 - 6}$ and the benzene analogues, PhX , at the B3LYP/6-311G* level of theory. Whilst the HOMO in $\mathbf{1}$ is essentially composed of the phenyl ring $\pi$ orbitals, the LUMO features an important contribution from the atoms of the cage ( $29 \%$ ) in addition to the phenyl $\pi^{*}$ system. These frontier orbitals are
stabilised relative to the analogous orbitals in benzene, as expected following the introduction of the electron-withdrawing carborane group (Fig. 4). The stabilising effect of the orbital contribution of the cage to the LUMO results in smaller HOMO-LUMO gaps in the cluster systems than in the benzene derivatives (Fig. 5).

The $N, N$-dimethylamino substituted compound 4 provides an example with which to discuss the influence of the substituents on the electronic structure of 1,2-diphenyl ortho carboranes relative to the parent system $\mathbf{1}$. The introduction of the electron-donating $\mathrm{NMe}_{2}$ group in 4 results in a separation of the HOMO which has appreciable $\mathrm{N}, \mathrm{N}$ dimethylamino character from the other occupied orbitals. In contrast, the HOMO of $\mathbf{1}$ lies closer to the other occupied orbitals. As indicated above, the LUMO and other closely lying unoccupied orbitals have appreciable cage carbon and phenyl ring character (Fig. 5). However, whilst the LUMO is evenly distributed over both phenyl rings in $\mathbf{1}$, it is more heavily localised on the unsubstituted ring in $\mathbf{4}$, as might be expected following the introduction of the strongly electron donating $\mathrm{NMe}_{2}$ group. The orbitals in the other donor substituted carboranes ( $\mathbf{3}, \mathbf{5}$ and $\mathbf{6}$ ) are similar to those of $\mathbf{4}$

Fig. 4 MO diagram for $\mathrm{PhCbC}_{6} \mathrm{H}_{4} \mathrm{X}$ and $\mathrm{PhX}\left(\mathrm{X}=\mathrm{H}, \mathrm{NMe}_{2}\right)$

Fig. 5 Selected frontier molecular orbitals for PhCbPh 1 and $\mathrm{PhCbC}_{6} \mathrm{H}_{4} \mathrm{NMe}_{2}$ 4. Numbers without parentheses represent orbital contributions from phenyl groups and cage

1

(Fig. 4). In contrast, the inductively electron withdrawing F group in $\mathbf{2}$ has little effect on the electronic structure, and the frontier orbitals of this species are similar to those of $\mathbf{1}$.

## UV-visible spectroscopy

The influence of the carborane cage contribution to the lowlying unoccupied orbitals in $\mathbf{1 - 6}$ should be apparent in the electronic absorption spectra of these compounds in comparison with the spectra of the analogous substituted benzenes. Electronic absorption spectra were recorded for the carborane series 1-6 from tetrahydrofuran solutions (Fig. 6, Table 4). To aid in the assignment of the observed transitions, TD-DFT computations were carried out on MP2-optimised geometries of these systems at the B3LYP/ $6-311 G^{*}$ level of theory. UV-visible spectra from the substituted benzenes PhX , also recorded as tetrahydrofuran solutions, are depicted for comparison (Fig. 6).

The parent compound $\mathbf{1}$ shows a strong band at 220 nm and very weak, vibrationally structured bands at 261,267 and 274 nm [57], similar to those found in benzene [58]. On the basis of the TD-DFT calculations, the HOMO-n ( $n=$ $0-3$ ) and LUMO (Fig. 5) are most heavily involved in the most intense absorption band, which approximates the phenyl-localised $\pi-\pi^{*}$ transitions. The spectrum of the fluoro compound 2 displayed a similar spectroscopic profile, confirming that the electron withdrawing F group has little effect on the electronic structure.

The UV-visible spectra of compounds 3-6 with elec-tron-donating substituents are generally red-shifted and of greater intensities than the benzene analogues PhX (Fig. 6). TD-DFT computations on these compounds 3-6 show that the bands correspond to transitions from the $\pi$-orbitals localised on the rings with electron-donating substituent X (donor) to the $\pi^{*}$ orbitals localised on the unsubstituted phenyl rings (acceptor).

## Electrochemical studies

The electrochemical behaviours of the diaryl-ortho-carboranes (1-6) were studied by cyclic voltammetry (CV) and square wave voltammetry (SWV) on a glassy carbon (GC) electrode in acetonitrile with 0.1 M tetrabutylammonium hexafluorophosphate ( $\mathrm{TBAPF}_{6}$ ) as supporting electrolyte. Table 5 reports the half-wave potentials $\left(E_{1 / 2}\right)$, calculated as the mean between cathodic and anodic peak potentials, and the cathodic to anodic peak separation, $\Delta E_{\mathrm{p}}$, in MeCN at $0.2 \mathrm{~V} / \mathrm{s}$ for the diaryl carboranes $\mathbf{1 - 6}$. The CV and SWV data of compounds $\mathbf{1 - 6}$ show two sequential quasireversible 1e reduction processes. As the scan rate is increased, the cathodic-to-anodic peak separation $\left(\Delta E_{\mathrm{p}}\right)$ of the first redox process $(0 /-1)$ increases more than the $\Delta E_{\mathrm{p}}$ of the second reduction $(-1 /-2)$, as shown in Fig. 7 for compounds $\mathbf{1}$ and $\mathbf{5}$ for illustrative purposes. It is therefore likely that the heterogeneous electron transfer rate of the second reduction is faster than the first.

Fig. 6 UV-vis spectra for carboranes 1-6 and their benzene analogues in THF

Unsurprisingly, the reduction potentials of $\mathbf{1 - 6}$ shift to more negative values as the substituent X becomes more electron donating, for example, the $E_{1 / 2}$ value of 4 ( $\mathrm{X}=$ $\mathrm{NMe}_{2}$ ) is approximately 100 mV more negative than that of $1(\mathrm{X}=\mathrm{H})$. Digital simulations of the experimental voltammograms were successfully achieved using a simple EE electrochemical mechanism; thermodynamic and kinetic parameters are summarised in Table 6, and illustrated, for example, for compound 1 (Fig. 8). Crucially, the observation of two distinct reduction processes for each member of the series $\mathbf{1 - 6}$ indicates that the thermodynamically stable
radical anions, which possess $[2 \mathrm{n}+3]$ skeletal electron counts, are a general feature of $C, C^{\prime}$-diaryl-ortho-carboranes [32]. However, isolated examples of carborane radicals with a [2n+3] skeletal electron count are extremely rare with only one structurally characterised to date [59].

## Conclusions

X-ray crystallographic studies for six derivatives $\mathrm{PhCbC}_{6} \mathrm{H}_{4} \mathrm{X}\left(\mathrm{X}=\mathrm{H}, \mathrm{F}, \mathrm{OH}, \mathrm{OMe}, \mathrm{NH}_{2}, \mathrm{NMe}_{2}\right) \mathbf{1}-\mathbf{6}$ show

small variations in the intra-cage $\mathrm{C}(1)-\mathrm{C}(2)$ bond lengths with the electronic nature of X , elongating when X is electron-releasing. These variations are much less pronounced than variations in compounds 1-X-2-Ph-1,2$\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{10}$ studied earlier [22]. It is remarkable that all crystals of the six carboranes studied here have $Z^{\prime}>1$, i.e. more than one independent molecule. Boron-11 NMR data on seven derivatives, $1-\left(4-\mathrm{XC}_{6} \mathrm{H}_{4}\right)-2-\mathrm{Ph}-1,2-\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{10}$ ( $\mathrm{X}=\mathrm{H}, \mathrm{F}, \mathrm{OMe}, \mathrm{NMe}_{2}, \mathrm{NH}_{2}, \mathrm{OH}, \mathrm{O}^{-}$) show variations in the antipodal boron (B12) chemical shift which correlate well with the electron-donating ability (Hammett $\sigma_{\mathrm{p}}$ values) of the substituent. The major bands observed in the UV-vis spectra of the $\mathrm{PhCbC}_{6} \mathrm{H}_{4} \mathrm{X}$ series $1-6(\mathrm{X}=\mathrm{H}, \mathrm{F}, \mathrm{OMe}$, $\mathrm{NMe}_{2}, \mathrm{NH}_{2}$ and OH ) are red-shifted by the cluster when compared to PhX ring systems; although the electronwithdrawing properties of the carborane cage contribute somewhat to the stabilisation of the HOMO, the carborane

contribution to the low-lying unoccupied orbitals involved in these transitions is more significant.

These structural and spectroscopic studies on compounds $1-\left(4-\mathrm{XC}_{6} \mathrm{H}_{4}\right)-2-\mathrm{Ph}-1,2-\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{10}$ have thus provided evidence of electronic communication between the substituent X and the carborane cage through the intervening phenylene link. Cyclic voltammetric studies also support the notion of interaction between the cage and the group X , with the reduction potentials of the cage tracking the electronic nature of X. These electrochemical studies also provide experimental evidence for the generality of cluster radical anions with $[2 n+3]$ skeletal electron counts.

## Experimental section

All reactions were conducted under dry nitrogen unless otherwise stated. Toluene was dried over sodium metal and distilled prior to use. Pyridine was dried and purified by distillation after standing over KOH. Elemental carbon, hydrogen and nitrogen analyses were performed using Exeter Analytical CE-440 or Carlo Erba Strumentazione EA model 1106 instruments. Mass spectra (MS) were recorded on a VG Micromass 7070E instrument under E.I conditions (EI) at 70 eV . Values of $M$ show the isotope range ${ }^{10} \mathrm{~B}_{\mathrm{n}}$ to ${ }^{11} \mathrm{~B}_{\mathrm{n}}$, including a ${ }^{13} \mathrm{C}$ contribution if observed. NMR spectra were measured using Varian Unity-300 ( $\left.{ }^{1} \mathrm{H},{ }^{11} \mathrm{~B},{ }^{13} \mathrm{C}\right)$, Bruker AM250 $\left({ }^{1} \mathrm{H},{ }^{13} \mathrm{C}\right)$, Bruker Avance $400\left({ }^{1} \mathrm{H},{ }^{11} \mathrm{~B},{ }^{13} \mathrm{C}\right)$ and/or Varian Inova $500\left({ }^{1} \mathrm{H}\right.$, ${ }^{11} \mathrm{~B}$ ) instruments. All chemical shifts are reported in $\delta$ (ppm) and coupling constants in Hertz. ${ }^{1}$ H NMR spectra were referenced to residual protio impurity in the solvent $\left(\mathrm{CDCl}_{3}, 7.26 \mathrm{ppm} ; \mathrm{CD}_{3} \mathrm{CN}, 1.95 \mathrm{ppm}\right) .{ }^{13} \mathrm{C}$ NMR spectra were referenced to the solvent resonance $\left(\mathrm{CDCl}_{3}\right.$,

Fig. 7 Cyclic voltammograms of 1,2-diphenyl-ortho-carborane (1) (left) and 1-(4-aminophenyl)-2-phenyl-ortho-carborane (5) (right) in acetonitrile at GC electrode with various scan rates

$\left.77.0 \mathrm{ppm} ; \mathrm{CD}_{3} \mathrm{CN}, 118.3 \mathrm{ppm}\right) .{ }^{11} \mathrm{~B}$ NMR spectra were referenced to external $\mathrm{Et}_{2} \mathrm{O} . \mathrm{BF}_{3}, \delta=0.0 \mathrm{ppm}$. UV-visible spectra were recorded in THF solutions with 2 mm path length UV cells on a Perkin Elmer Lambda 900 UV-visNIR spectrometer.

Phenylethynylcopper, $\mathrm{PhC} \equiv \mathrm{CCu}$, and 6,9 -bis(acetonitrile)decaborane, $\mathrm{B}_{10} \mathrm{H}_{12}(\mathrm{NCMe})_{2}$, were prepared as previously described [60]. The diarylacetylenes, 4$\mathrm{XC}_{6} \mathrm{H}_{4} \mathrm{C} \equiv \mathrm{CPh}$, were synthesised from phenylethynylcopper and the appropriate aryl iodide in pyridine using the literature method described for methyl 4-phenylethynylbenzoate [60]. The isolated yields obtained for the diarylethynes where $\mathrm{X}=\mathrm{F}, \mathrm{OMe}, \mathrm{NMe}_{2}$ and $\mathrm{NO}_{2}$ were 64,67 , 40 and $70 \%$, respectively. Compound 1 was synthesised from diphenylethyne and $\mathrm{B}_{10} \mathrm{H}_{12}(\mathrm{NCMe})_{2}$ in $72 \%$ yield using the literature method described for a related diaryl carborane $\mathrm{PhCbC}_{6} \mathrm{H}_{4} \mathrm{CO}_{2} \mathrm{Me}$ [60].

For cyclovoltammetric studies, acetonitrile was distilled over calcium hydride just before use. Tetrabutylammonium hexafluorophosphate $\left(\mathrm{Bu}_{4} \mathrm{NPF}_{6}\right)$ was obtained as metathesis reaction between $\mathrm{KPF}_{6}$ (Fluka) and tetrabutylammonium iodide (Aldrich), re-crystallised three times from 95\% ethanol and dried in vacuum oven at $110{ }^{\circ} \mathrm{C}$ overnight. Electrochemistry was performed in a three-electrode cell using a potentiostat AMEL 7050 and an EG\&G PAR 273 electrochemical analyser, both connected to a PC. The reference electrode was 3 M KCl calomel electrode, the

auxiliary electrode a platinum wire and the working electrode a GC. Positive feedback $i R$ compensation was applied routinely. All measurements were carried out under Ar in anhydrous deoxygenated solvents. Ferrocene $\left(F_{\mathrm{c}}\right)$ was used as internal standard, and potentials are reported against the $F_{\mathrm{c}}(0 /+1)$ redox couple, that in our conditions is $E(0 /+1)=0.395 \mathrm{~V}$.

## Syntheses

Synthesis of 1-(4-FC $\left.\mathrm{F}_{6} \mathrm{H}_{4}\right)-2-\mathrm{Ph}-1,2-\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{10}, 2$
A stirred slurry of $\mathrm{B}_{10} \mathrm{H}_{12}(\mathrm{NCMe})_{2}(1.58 \mathrm{~g}, 7.8 \mathrm{mmol})$ in toluene ( 25 ml ) was treated dropwise with a solution of 4$\mathrm{FC}_{6} \mathrm{H}_{4} \mathrm{C} \equiv \mathrm{CPh}(1.35 \mathrm{~g}, 7.8 \mathrm{mmol})$ in toluene ( 20 ml ). The mixture was heated at reflux for 18 h , giving an orange-red solution. Removal of the solvent in vacuo afforded an orange solid. The solid was treated with $\mathrm{MeOH}(30 \mathrm{ml})$ and left to stir overnight to destroy any unreacted decaborane. The solvent was removed and the residue extracted with hexane. The hexane extracts were filtered and the filtrate cooled $\left(-30^{\circ} \mathrm{C}\right)$ to afford large colourless crystals $(1.15 \mathrm{~g}$, $47 \%$ ) of the fluoro compound 2. M.p. $136-7^{\circ} \mathrm{C}$. Found: C,

Fig. 8 Experimental (green) and simulated (red) CV at $0.1 \mathrm{~V} / \mathrm{s}$ of 1,2-diphenyl-ortho-carborane (1) in acetonitrile

Synthesis of 1-(4-MeOC $\left.{ }_{6} \mathrm{H}_{4}\right)-2-\mathrm{Ph}-1,2-\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{10}, 3$
A solution of $4-\mathrm{MeOC}_{6} \mathrm{H}_{4} \mathrm{C} \equiv \mathrm{CPh}(10.3 \mathrm{~g}, 0.05 \mathrm{~mol})$ in toluene ( 60 ml ) was added to a stirred slurry of $\mathrm{B}_{10} \mathrm{H}_{12}(\mathrm{NCMe})_{2}(10.1 \mathrm{~g}, 0.05 \mathrm{~mol})$ in toluene $(60 \mathrm{ml})$. The mixture was heated at reflux point for 24 h , during which time hydrogen was evolved and the solution became dark red in colour. After allowing the reaction mixture to cool to $20^{\circ} \mathrm{C}$, the solution was diluted with $\mathrm{MeOH}(60 \mathrm{ml})$ MeOH to destroy any unreacted decaborane. The solvents were removed in vacuo and the solid residue which was obtained crushed into a powder. This solid was subjected to Soxhlet extraction with hexane ( 80 ml ) for 24 h . The crystals ( $6.4 \mathrm{~g}, 40 \%$ ), formed after cooling and slow evaporation of the hexane extract, were identified as compound 3 [43]. M.p. $101-2{ }^{\circ} \mathrm{C}$. Found: C, 55.4, H, $6.6 \% \mathrm{C}_{15} \mathrm{H}_{22} \mathrm{~B}_{10} \mathrm{O}$ requires C, $55.2, \mathrm{H}, 6.8 \%$. MS ( $\mathrm{EI}^{+}, \mathrm{m} /$ $z):[\mathrm{M}]^{+} 320-329$; observed 326 (100). Synthesis of 1-(4-Me $\left.\mathrm{NC}_{6} \mathrm{H}_{4}\right)-2-\mathrm{Ph}-1,2-\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{10}, 4$

A solution of $4-\mathrm{Me}_{2} \mathrm{NC}_{6} \mathrm{H}_{4} \mathrm{C} \equiv \mathrm{CPh}(3.32 \mathrm{~g}, 0.015 \mathrm{~mol})$ in toluene ( 40 ml ) was added to a stirred slurry of $\mathrm{B}_{10} \mathrm{H}_{12}(\mathrm{NCMe})_{2}(3.03 \mathrm{~g}, 0.015 \mathrm{~mol})$ in toluene $(50 \mathrm{ml})$.

The mixture was slowly heated to reflux point, during which time hydrogen gas was evolved and the solution turned red. After heating at reflux point for 26 h , the dark red solution was cooled and diluted with $\mathrm{MeOH}(40 \mathrm{ml})$. The solvents were removed in vacuo, the solid residue crushed into a powder and extracted with boiling hexane. The combined extracts were allowed to cool and the yellow crystals ( $2.08 \mathrm{~g}, 41 \%$ ) that formed were identified as the desired dimethylamino compound 4. M.p. $158-9^{\circ} \mathrm{C}$. Found: C, $57.0, \mathrm{H}, 7.1, \mathrm{~N}, 3.8 \% \mathrm{C}_{14} \mathrm{H}_{25} \mathrm{~B}_{10} \mathrm{~N}$ requires $\mathrm{C}, 56.6, \mathrm{H}$, 7.4, N, 4.1\% MS (EI,$m / z$ ): [M] ${ }^{+} 333-341$; observed 339 (100). Synthesis of 1-(4-HOC $\left.\mathrm{H}_{6}\right)-2-\mathrm{Ph}-1,2-\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{10}, 6$
Dry hydrogen chloride was bubbled through pyridine $(8 \mathrm{ml})$ and the resulting solid heated to $170{ }^{\circ} \mathrm{C}$. After 2 h and with the temperature still at $170{ }^{\circ} \mathrm{C}, 1-\left(4-\mathrm{MeOC}_{6} \mathrm{H}_{4}\right)-2$ -$\mathrm{Ph}-1,2-\mathrm{C}_{2} \mathrm{~B}_{10} \mathrm{H}_{10} 3(1.96 \mathrm{~g}, 6 \mathrm{mmol})$ of was added and the temperature raised to $200^{\circ} \mathrm{C}$ for 3 h . The reaction mix was left to cool to give a white solid, of which a large part was dissolved in water to leave a gum-like solid. The undissolved solid was collected by filtration and dried in vacuo before being dissolved in diethyl ether, dried over $\mathrm{MgSO}_{4}$ and filtered. The ether was removed in vacuo to yield a white solid which was re-crystallised from hexane to give large colourless crystals ( $1.24 \mathrm{~g}, 66 \%$ ) of the hydroxy compound $6[43,62]$. M.p. $136-7^{\circ} \mathrm{C}$. Found: C, $54.0, \mathrm{H}, 6.6 \% \mathrm{C}_{14} \mathrm{H}_{20} \mathrm{~B}_{10} \mathrm{O}$ requires $\mathrm{C}, 53.9, \mathrm{H}, 6.4 \%$. ## Crystallography

X-ray diffraction experiments were carried out on threecircle Bruker diffractometres with a SMART 1K or (for $\mathbf{1}$ and 3) SMART 6K CCD (for $\mathbf{2}$ and 4-6) area detectors using graphite-monochromated $\mathrm{Mo}-K_{\alpha}$ radiation ( $\lambda=0.71073 \AA$ ) and a Cryostream open-flow $\mathrm{N}_{2}$ cryostat (Oxford Cryosystems). Full sphere of reciprocal space (for 4, a hemisphere) was covered by three to four sets of narrow-frame $\left(0.3^{\circ}\right) \omega$ scans, each set with different $\varphi$ angle. The structures were solved by direct methods and refined by full-matrix least squares against $F^{2}$ of all data using SHELXTL software [63]. Non-hydrogen atoms were refined in anisotropic approximation. The ordered hydroxyl H atoms in 6 and amino $H$ atoms in 5 were refined in isotropic approximation; the remaining H atoms were included as riding in idealised positions. Crystal data and experimental details are listed in Table 7. Full crystallographic data, excluding structure factors, have been deposited at the Cambridge Crystallographic Data Centre.

## Computations

All ab initio computations were carried out with the Gaussian 03 package [64]. The geometries discussed here were optimised at the HF/6-31G* and B3LYP/6-31G* levels of theory with no symmetry constraints. Frequency calculations were computed on these optimised geometries
at the corresponding levels and shown to have no imaginary frequencies. Optimisation of these geometries were then carried out at the MP2/6-31G* level of theory.

Calculated NMR shifts at the GIAO-B3LYP/6-311G* level were obtained from these MP2-optimised geometries. Theoretical ${ }^{11} \mathrm{~B}$ chemical shifts at the GIAO-B3LYP/6-311G*//HF-B3LYP-MP2/6-31G* level were referenced to $\mathrm{B}_{2} \mathrm{H}_{6}(16.6 \mathrm{ppm}[65])$ and converted to the usual $\mathrm{BF}_{3} . \mathrm{OEt}_{2}$ scale: $\delta\left({ }^{11} \mathrm{~B}\right)=102.83-\sigma\left({ }^{11} \mathrm{~B}\right)$. The ${ }^{13} \mathrm{C}$ and ${ }^{1} \mathrm{H}$ chemical shifts were referenced to TMS: $\delta\left({ }^{13} \mathrm{C}\right)=179.81-\sigma\left({ }^{13} \mathrm{C}\right) ; \delta$ $\left({ }^{1} \mathrm{H}\right)=32.28-\sigma\left({ }^{1} \mathrm{H}\right)$. Electronic structure and TD-DFT computations at the B3LYP/6-311G* level of theory were carried out on these MP2-optimised geometries.

Acknowledgements We thank the EPSRC and Regione Piemonte for generous financial support and the University of Durham High Performance Computing centre for computing facilities.
