1. Introduction

Gears are widely used in metapoid systems, and many studies have examined gear dynamics. To analyze the dynamic behavior of crear schem, the nonlinearity of mesh stiffness and backlash must be considered. Several works have modeled for systems, including complicating effects, such as nonlinear mesh stiffness and backlash [1–3], conlinear mesh damping [4], sliding friction force [5], and shaft flexibility [6]. Tooth modification [7], planting in plantary gears [8], and optimizing boundary conditions [9,10] have been applied to reduce printing whether the systems.

One-by clutch are may used in the serpentine belt systems of automobiles and heavy vehicles to mitigate the torsional vibration generated by periodic engine pulsations. A one-way clutch engages or disengates according to the relative angular speed between the driving and driven elements and acts as a vibration proper [1]. It is reasonable to think that a one-way clutch might reduce the vibration in a gear system, such that a prepentine belt system, by suppressing the torsional vibration of the gear system. However, I am unaware or any other studies on the dynamics of a gear pair with a one-way clutch.

This study focused on the dynamic behavior of spur gear pairs with a one-way clutch. The dynamic responses were studied over a wide frequency range by speed sweeping to verify the nonlinear behavior, such as softening nonlinearity, around the natural frequency. Since the oscillating part of the dynamic transmission

error (DTE) is the main source of noise and vibration in gear systems [12], the oscillating components of the DTE were compared as the main dynamic response.

2. Mathematical model

The system consisted of two gears mounted on input and output shafts through a one-way clutch (Fig. 1). The gears were perfect involute spur gears with no modifications. The torsional flexibility of both shafts was neglected, and the inertias of the input shaft and driver and those of the output shaft and load were lumped together, respectively.

Gears 1 and 2 had base circles of radii r_1 and r_2 and mass moments of inertia of I_1 and I_2 , respectively; I_i and I_0 were the mass moments of inertia of the driver and load, respectively. The pair of g are was odeled using two disks coupled with a nonlinear mesh stiffness and mesh damping; k(t) and c are the pair of g are the pair, stiffness and damping coefficient of the gear pair, respectively. The total backlash was 2b; θ , θ , and represented the vibrations of the driver, load, and gears 1 and 2 about the nominal rigid body θ , ion, respectively. We were the stiffness and damping coefficient of the one-way clutch, respectively.

The torque and speed of the input shaft were assumed to be constant and control tole, and the two gears and output shaft were assumed to show rotational displacement only. The one-way club, was modeled as a nonlinear spring with discontinuous stiffness, i.e., zero stiffness for the congaged clutch and finite linear stiffness for the engaged clutch. When the rotation of the driver excees the order 1, the clutch is engaged and clutch torque is transmitted from the driver to gear 1. When the protection of the driver is less than the rotation of gear 1, then the clutch is disengaged and no order is transmitted [11]. The same occurs between gear 2 and the load.

The equations of motion of the two gears and load represented as

$$I_{1}\ddot{\theta}_{1} + c[r_{1}\dot{\theta}_{1} - v_{2}\dot{\theta}_{2}] + v_{2}\beta(t) = c_{1}(t),$$

$$I_{2}\ddot{\theta}_{2} - c[r_{1}\dot{\theta}_{1} - r_{2}\dot{\theta}_{2}] \quad k(t)\beta(t) = -T_{c2}(t),$$

$$I_{0}\ddot{\theta}_{0} = T_{c2}(t) \quad T_{0}.$$
(1)

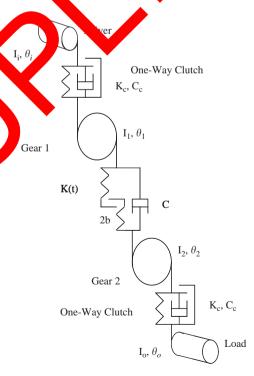

Fig. 1. Schematic diagram of a gear pair with a nonlinear one-way clutch at both sides of the driving and driven shafts.

Forcing terms $T_{c1}(t)$ and $T_{c2}(t)$ are the torques transferred by clutch 1 to gear 1, and by clutch 2 to the load, respectively. They are piecewise linear functions and are represented as

$$T_{c1}(t) = \begin{cases} K_c(\theta_i - \theta_1) + C_c(\dot{\theta}_i - \dot{\theta}_1), & \text{when } \theta_i > \theta_1 \\ 0, & \text{when } \theta_i \leqslant \theta_1 \end{cases},$$

$$T_{c2}(t) = \begin{cases} K_c(\theta_2 - \theta_o) + C_c(\dot{\theta}_2 - \dot{\theta}_o), & \text{when } \theta_2 > \theta_o \\ 0, & \text{when } \theta_2 \leqslant \theta_o \end{cases},$$

$$(2)$$

where T_o is the static load torque. The vibration of the driver θ_i was assumed to be zeron this study.

In this study, both the external forces and the mesh stiffness and backlash were regarded as body nonlinear. The mesh stiffness variation k(t) was the time-varying mesh stiffness obtained by turning a rectangular wave [13]:

$$k(t) = k_o + \sum_{r=1}^{R} k_r \cos(2\pi r f_m t - \phi_r),$$

$$k_o/k_{tp} = ICR,$$

$$k_r/k_{tp} = \sqrt{2 - 2\cos[2\pi r (ICR - 1)]},$$

$$\phi_r = \frac{1 - \cos[2\pi r (ICR - 1)]}{\sin[2\pi r (ICR - 1)]},$$
(3)

where f_m is the mesh frequency, ICR is the involute confact ratio, k_0 is the average mesh stiffness value and k_r and ϕ_r are the rth Fourier coefficient and phase angle of k(t), respectively. Here, R = 5.

Gear backlash nonlinearity was modeled as a liecew linear fultion.

$$\beta(t) = \begin{cases} r_1 \theta_1 - r_2 \theta_2 - b, & \text{when } r_1 \theta_1 - r_2 \theta_2 > b \\ r_1 \theta_1 - r_2 \theta_2 + b, & \text{en } r_1 \theta_1 - r_2 \theta_2 < -b \\ 0, & \text{then } |r_1 \theta_1 - r_2 \theta_2| \le b \end{cases}$$
 (4)

The damping coefficients c of the clutch were calculated as

$$C = 2\zeta \sqrt{k_o/[(r_1^2/I_1) + (r_2^2/I_2)]},$$

$$C_c = 2\zeta_c \sqrt{K_c I_i},$$
(5)

where ζ and ζ_c are the damph, ratios of the tooth mesh and clutch, respectively [14]. For comparison, he behavior of a gear pair system mounted on the shaft directly without a one-way clutch was also analyzed. Requation of motion of gears 1 and 2 without a one-way clutch can be expressed as

$$(I_1 + I_i)\ddot{\theta}_1 + c[r_1\dot{\theta}_1 - r_2\dot{\theta}_2] + k(t)\beta(t) = T_i,$$

$$(I_2 + I_o)\ddot{\theta}_2 - c[r_1\dot{\theta}_1 - r_2\dot{\theta}_2] - k(t)\beta(t) = -T_o,$$
(6)

where T_i be starting input torque.

The DTE cefined as $(r_1\theta_1 - r_2\theta_2)$.

Because numerical integration gave results in good agreement with the analytical methods of nonlinear behavior analysis [1,3], the solutions were obtained using direct time domain numerical integration (fifth-order Runge-Kutta algorithm) in this study.

3. Parametric study

The primary purpose of this work was to examine the nonlinear dynamic response of a single gear pair with a one-way clutch. Table 1 shows the dimensions of an identical gear pair used in previous research [2,13] for comparison.

Table 1 Dimensions of the gears

Teeth number	50
Module	$0.003{ m m}$
Pressure angle	20°
Face width	$0.02\mathrm{m}$
Modulus of elasticity	$207 \times 10^9 \mathrm{N/m^2}$
Density	$7600 \mathrm{kg/m^3}$
Base radius	$0.07047 \mathrm{m}$
Backlash (2b)	$400 \times 10^{-6} \mathrm{m}$
Mass	2.8 kg
Mass moment of inertia $(I_1 = I_2)$	$7.5 \times 10^{-3} \mathrm{kg} \mathrm{m}^2$

The average mesh stiffness k_o was 462.1×10^6 N/m, and the contact ratio CR) Vec 1.75. The camping ratio of the tooth mesh and clutch were $\zeta = 0.07$ and $\zeta_c = 0.01$, respectively. The input torque T_i was 150 N m, and the load torque was $T_o = r_2/r_1 \times T_i$. The stiffness of the one-way clutch was selected as 1.50×10^3 (N m/rad) to produce a torque equal to the input torque at a clutch displacement 10.50×10^3 (N m/rad) to load were kept the same as those of the gears.

To detect jump phenomena, an increasing and decreasing frequency v ρ was executed at a constant ratio for a wide range across the first natural frequency. To get stable data at r a speed change, 1×10^5 time step data were discarded before averaging was performed. The time step was 10^{-5} s for all conditions. Fig. 2 shows the flowchart of the algorithm for numerical integration used at this study.

The oscillating dynamic transmission error (OTE) component at root mean square (rms) of DTE at a specific constant speed were defined as

ODE
$$= \sqrt{\frac{1}{N} \sum_{i=1}^{N} (DTE_{i+1} - DTE_{i})^{2}},$$
run of DTE
$$= \sqrt{\frac{1}{N} \sum_{i=1}^{N} (DTE_{i})^{2}},$$
(7)

where $DTE_i = r_1\theta_1(t_i) - r_2\theta_2(t_i)$ and N_i the total number of time steps used for averaging, which was 1×10^4 in this study. The calculated natural frequency was around 2700 Hz. Varying parameters such as gear damping ratio, contact ratio, acklash, and load inertia ratio, ODTE of various clutch conditions were compared with that of NC condition.

Fig. 3 shows in DTE cape of the gear sets under four conditions: no clutch (NC), clutch at the driving shaft of y (CI), clutch at the driven shaft only (CO), and clutch at both shafts (CB). The results predicted multiple resonances, oftening nonlinearity, kink (onset of contact loss), and jump phenomena, which are typical in a nonlinear gear system, and generally agreed qualitatively with the results of Parker et al. [2]. A clear softening realinearity occurred as the peak bended to the left. The difference is thought due to the value of the shadoneria and backlash not mentioned in their study.

Over the entire frequency range, ODTE components could be reduced if a one-way clutch were installed at either one shaft only or both shafts. Primary resonance was evident for a mesh frequency of $f_m \approx f_n$ 2700 Hz.

In condition CB, the multiple solution bands were narrower than in the other conditions, and the overlap range shifted to a higher frequency due to decreased inertia separated by the one-way clutch on both sides. In contrast, the overlap frequency range did not change very much when only one clutch was installed. The overlap frequency depends on the clutch conditions.

Condition CO showed unstable double-jump down when the speed was decreasing. Because this kind of double-jump down disappeared for other system parameters (Figs. 6, 8, 11 and 12), the double-jump down phenomena in condition CO appeared to depend on the system parameters.

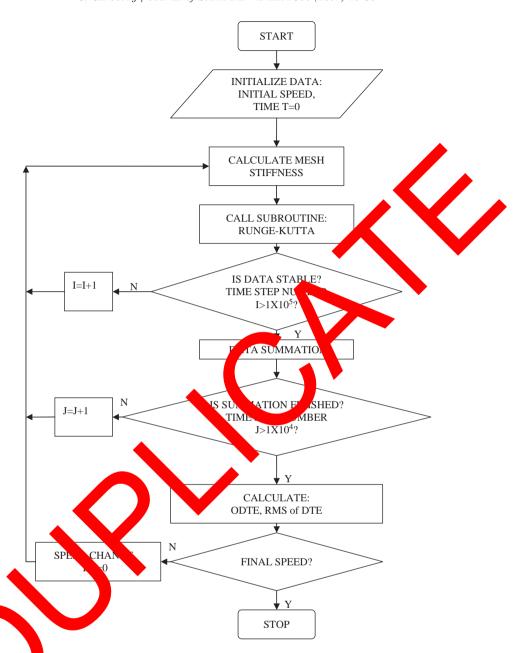

Fig. 2. Flowchart of the algorithm for numerical integration.

Fig. 4 shows be acceleration response (oscillating component) of the driving and driven gears under various clutch conditions. The results predicted multiple resonances, stiffening nonlinearity, and jump phenomena. In contrast to the DTE responses, the peak value of the alternating components of acceleration in condition CB was higher than in condition NC due to the intermittent impulsive engagement of the elements by the clutch. The responses of both gears were the same in condition CB. In the other conditions, however, the responses of the gears differed. The values for gear 1 in conditions NC and CI were higher than in condition CO. The values for gear 2 in condition CO were higher than in conditions NC and CI. The dynamics of the one-way clutch had a dominant effect on the gear installed near the clutch.

Fig. 5 shows the displacements of the two gears in conditions NC and CB. With NC (a), the driving gear (gear 1) maintains forward displacement and the driven gear (gear 2) maintains backward displacement, and

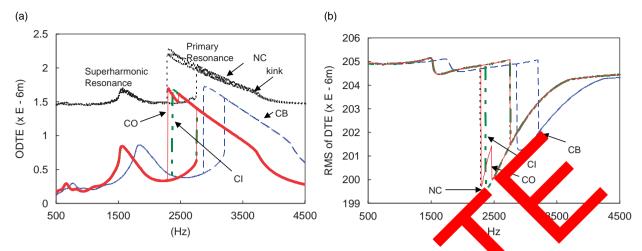

Fig. 3. DTE response of a gear pair system: (a) ODTE component and (b) D

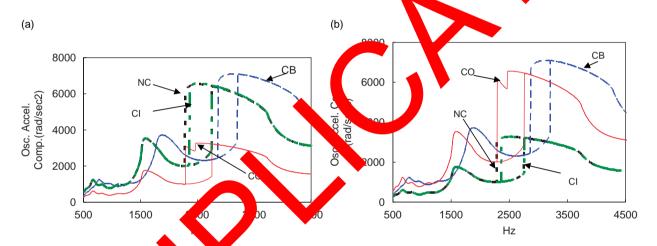

Fig. 4. A deration esponses for various clutch conditions: (a) gear 1 and (2) gear 2.

the total difference, the displacements equals DTE. With a clutch on both sides (b), all gears and the load maintain a backward displacement equal to the backlash plus clutch compression. The positions of the elements are an est in tight auring frequency sweeping. Relatively large variations occurred at the jump down for quency (c). These trends were similar under conditions CI and CO which were not presented here.

Fig. shows the DeE responses of various clutch conditions for a tooth mesh damping ratio of $\zeta = 0.03$, while keeping the over parameters nominal. With decreased damping, the width of the overlap band increased and the jet p down frequency shifted toward lower frequencies. A new overlap band due to superharmonic resolute occurred, the double-jump down in condition CO at the first resonance frequency disappeared, and decreased damping increased the nonlinearity of the system.

Fig. 7 shows the DTE responses of condition NC, demonstrating the effects of load inertia. Keeping the inertias of the driver and two gears constant at the same value, the inertia of the load varied from one-tenth to ten times that of the other elements. The DTE responses depended dominantly on the load inertia in condition NC. As the load inertia increased, the overlap band shifted to lower frequencies.

Fig. 8 shows the DTE responses of various clutch conditions, demonstrating the effects of load inertia. Keeping the inertias of the driver and two gears constant at the same value, the inertia of the load was varied from one-tenth to ten times that of the other elements. In conditions CB and CO, the load inertia had little effect on the DTE responses. In condition CI, however, the overlap range shifted to a much lower frequency as

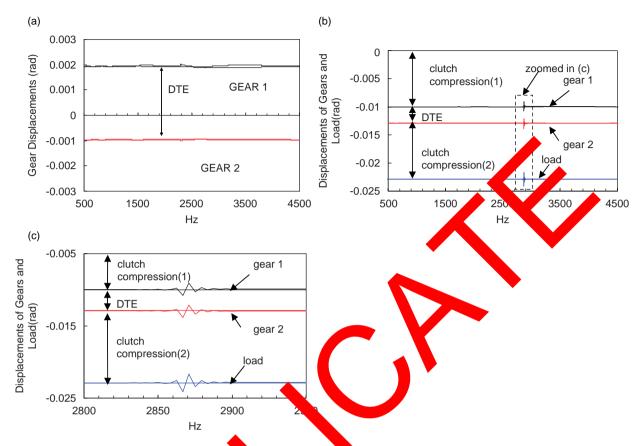

Fig. 5. Positions of the gears d load: Condition (NC, (b) CB, and (c) zoomed area of (b).

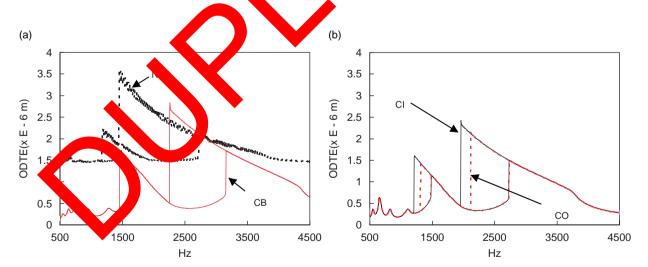

Fig. 6. ODTE responses of various clutch conditions for $\zeta = 0.03$: (a) NC and CB, and (b) CI and CO.

the inertia increased, but the width did not change much. Installing clutches at both shafts effectively suppressed the negative effects of a large load inertia. When the load inertia ratio was high, a new nonlinear jump occurred at the super-harmonic frequency in condition CI. A one-way clutch installed at the input shaft had little effect on the response of the gear system with load inertia variation. In condition CO, the double-jump down disappeared.

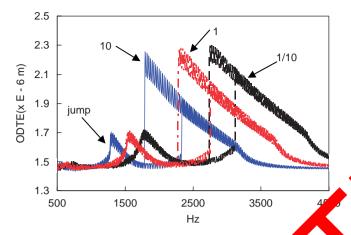

Fig. 7. ODTE responses of condition NC for various load in tia ratio

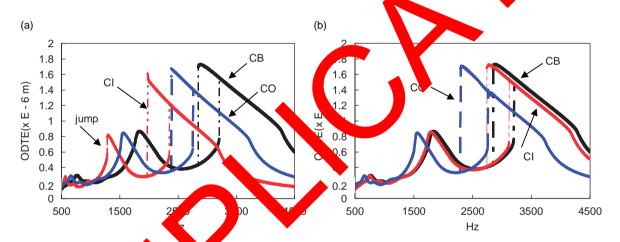

Fig. 8. ODTE reconses on four clutch conditions for different load inertia ratios: (a) 10 and (b) 1/10.

Fig. 9 shows the De T respons on the no-clutch condition for various backlashes, while keeping the other parameter rates against The scillating DTE components decreased with the backlash. When the backlash was very small (5 μc), hardening nonlinearity due to double-side contact appeared, demonstrating that torsion wibration greater than the backlash causes double-side contact. However, such double-side contact would rate v occur it a real system, because the backlash recommended by design handbooks (such as the American Gers Manufacturers Assoc. (AGMA)) for the gear dimension used in this study was much greater than 5 μm. The verlap range and jump frequency were barely affected by backlash.

Fig. 10 shows the DTE responses of various conditions for a backlash of 5 μm. The responses under all clutch conditions, except for condition CB, showed double-side contact. In contrast, double-side contact nonlinearity did not occur in condition CB. The clutches installed at both shafts seemed to be effective in preventing potential double-side contact.

Fig. 11 shows the DTE response under four clutch conditions for various contact ratios, while keeping the other parameters nominal. The effects of the contact ratio on the DTE were the same in the clutch and noclutch conditions. There should be an optimum contact ratio in order to minimize ODTE.

Fig. 12 shows the DTE responses in condition CO for various load inertia ratios. It shows that the unstable double-jump down phenomena occurs in a specific range of the load inertia ratios.

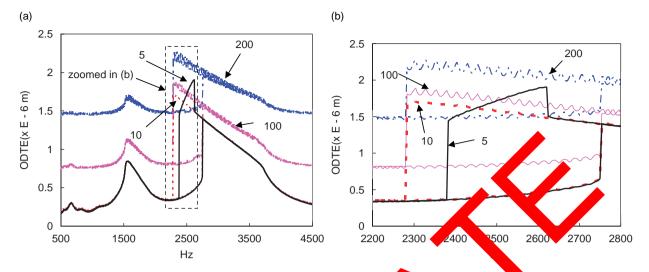

Fig. 9. ODTE responses in the no-clutch condition for various backlashes (() ODTE and (b) comed area of (a).

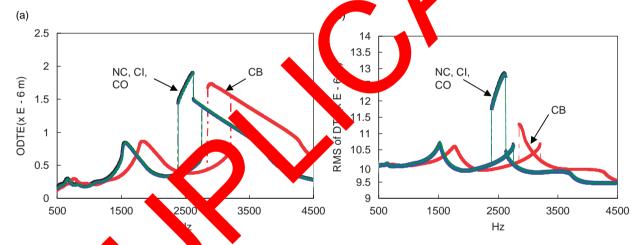

Fig. 10. ΣE responses of arrious clutch conditions for a backlash of 5 μm: (a) ODTE and (b) rms of DTE.

Though every couch conditions are effective for reducing ODTE, CB condition is more effective for mitigating the negative effects of various parameter changes (Table 2). Hence, CB condition only was simulated bereinafter

Fig. 13 was at DTE responses in condition CB for various backlashes. The DTE responses barely depended on a backlash variation in condition CB.

Fig. 14 shows the DTE responses of condition CB for various torques, while keeping the other parameters nominal. The overlap range and frequency of jump and kink did not depend on the torque. The peak value was proportional to the torque. These trends were similar under other clutch conditions which were not presented here.

Fig. 15 shows the DTE and displacement responses in condition CB for various clutch stiffnesses, while keeping the other parameters at nominal values. The stiffness was normalized relative to the nominal value $1.5 \times 10^4 \,\mathrm{N}\,\mathrm{m/rad}$. When the clutch stiffness exceeded a specific range, the response lost its typical nonlinear phenomena and became very unstable. The gear displacement increased almost linearly as a function of time during frequency sweeping. Increased displacement resulted from the impulsive torque induced by a large

various clutch dampin ratios. The DTE responses in condition CB depended little on clutch damping. These trends were summarined on a constant CO which were not presented here.

4. Con sions

This study varied whether a one-way clutch is effective for reducing the torsional vibration of a gear system using a fired gear model considering only rotational motion. A numerical integration method was used to solve the equations of motion.

The gear system with a one-way clutch showed typical nonlinear behavior, such as softening nonlinearity and jump phenomena, as in the system without a one-way clutch. However, the oscillating DTE component of the system with a one-way clutch was reduced over the entire frequency range. Installing a one-way clutch on both sides of the gear system shifted the overlap frequency range to higher frequencies, and was more effective at mitigating the negative effects of variation in several parameters than installing a clutch at the input or output side only. The stiffness of the one-way clutch had a great effect on the behavior of the gear system, and it must be kept under a specific value for a stable response. Nevertheless, clutch damping had little effect on the behavior of the gear system. The effects of mesh damping, the contact ratio, and torque on a gear system

with a one-way clutch were the same as in a gear system with no clutch. All analytical results presented in this study should be verified through further experimentation.
