**Abstract** This study investigates two lanthanide compounds ( $\text{La}^{3+}$  and  $\text{Sm}^{3+}$ ) obtained in water/ethyl alcohol solutions employing the anionic surfactant diphenyl-4-amine sulfonate (DAS) as ligand. Both sulfonates were characterized through IR, TG/DTG ( $\text{O}_2$  and  $\text{N}_2$ ). The thermal treatment of both compounds at 1273 K under air leaves residues containing variable percentages of lanthanide oxysulfide/oxysulfate phases shown by synchrotron high-resolution XRD pattern including the Rietveld analysis. The phase distributions found in the residues evidence the differences in the relative stability of the precursors.

## Introduction

The importance of the lighter lanthanide oxysulfate and oxysulfide systems ( $\text{Ln} = \text{La}, \text{Pr}, \text{Nd}$  and  $\text{Sm}$ ) arises from their applications in semiconductors, phosphorescent material design, X-ray computerized tomography, oxygen storage, and radiation detection [1–8]. Some of these applications are based on the reversible capability of the conversion shown by lanthanide oxysulfates/oxysulfides [1–3]. Lanthanide oxysulfates ( $\text{Ln}_2\text{O}_2\text{SO}_4$ )/oxysulfides ( $\text{Ln}_2\text{O}_2\text{S}$ ) (where  $\text{Ln} = \text{La}, \text{Pr}, \text{Nd}, \text{Sm}, \text{Eu}$ , and  $\text{Gd}$ ) have been produced from the thermal decomposition of hydrated lanthanide sulfates at temperatures  $>1073$  K for 5 h under  $\text{N}_2$  or air [1, 8]. Subsequent reduction of as prepared  $\text{Ln}_2\text{O}_2\text{SO}_4$  under a  $\text{H}_2$  flow ( $3.9 \text{ mol mol}^{-1}$ ) at 1073 K leads to an oxysulfide  $\text{Ln}_2\text{O}_2\text{S}$  ( $\text{Ln} = \text{La}, \text{Nd}, \text{Pr}$  and  $\text{Sm}$ ) single phase [1, 2]. The reversibility for some oxysulfides  $\text{Ln}_2\text{O}_2\text{S}$  ( $\text{La}, \text{Nd}$  and  $\text{Sm}$ ) can be achieved in the temperature interval of 1073–1173 K under 2 (mol of  $\text{O}_2$ )  $\text{mol}^{-1}$ . Differently, the re-oxidation of the oxysulfide  $\text{Pr}_2\text{O}_2\text{S}$  ( $\text{S}^{2-}$ ) to oxysulfate  $\text{Pr}_2\text{O}_2\text{SO}_4$  ( $\text{S}^{6-}$ ) occurs at temperatures  $<873$  K [1–3]. Atypically, the thermal treatment of cerium sulfate hydrated under  $\text{O}_2$  flow produces only the oxide [1, 2, 7, 8].

Lanthanide oxysulfides  $\text{Ln}_2\text{O}_2\text{S}$  ( $\text{Ln} = \text{Sm}, \text{Eu}$ ) can also be directly obtained by thermal treatment of the oxides  $\text{Ln}_2\text{O}_3$  at 573 K for 24 h under a flow of  $\text{CS}_2/\text{Ar}$  and low partial pressure of  $\text{O}_2$  or also by the solid state reaction of  $\text{CuFeS}_2$  with  $\text{Sm}_2\text{O}_3$  [4, 5].

In addition, nanocrystals of  $\text{EuO}_2\text{S}$  have been produced from the thermal decomposition of  $\text{Eu}[(\text{phen})-(\text{ddtc})_3]$  (where phen = phenatroline and ddtc = diethyldithiocarbamate) using  $\text{O}_2$  as oxidizer during the nucleation and growth process of the  $\text{Eu}_2\text{O}_2\text{S}$  nanocrystals. In the absence of protective conditions, the morphology of the  $\text{Eu}_2\text{O}_2\text{S}$  can be modulated by means of surfactant selection [6].

The direct interaction between the  $\text{La}^{3+}$  and  $\text{Fe}^{3+}$  ions and the anionic surfactant diphenyl-4-amine sulfonate (DAS) has already been studied [9, 10]. In these reactions, the metallic ions interact directly with the negative and partial charges formed by the electronic displacement inside the ligand rings toward the oxygen atoms of the sulfonate group. Under thermal treatment and atmosphere control, this effect will be sufficiently enhanced to allow the redox site  $\text{S}^{6+}$  of oxysulfate  $\text{M}_2\text{O}_2\text{SO}_4$  to be reduced to  $\text{S}^{2-}$ , to give the oxysulfide  $\text{M}_2\text{O}_2\text{S}$  [1–3, 6, 9]. This effect can even achieve the reduction of  $\text{Fe}^{3+}$  in the aqueous solution [10].

Here, we compare the arrangement of the surfactant molecules around of the metallic ions  $\text{Sm}^{3+}$  and  $\text{La}^{3+}$  with the oxysulfate/oxysulfide phase distribution rate. Experimentally, the  $\text{Sm}^{3+}$  diphenylamine-4-sulfonate was produced by reaction between  $\text{Sm}^{3+}$  sulfate hydrated and  $\text{Ba}^{2+}$  diphenylamine-4-sulfonate in water/ethyl alcohol solution and characterized through IR and TG/DTG ( $\text{O}_2$  and  $\text{N}_2$ ). The  $\text{La}^{3+}$  sulfonate utilized here was previously synthesized using the ligand  $\text{Na}^+$  diphenyl-4-amine sulfonate under the same operational conditions and also characterized through IR and TG/DTG ( $\text{O}_2$  and  $\text{N}_2$ ) [9]. Then, both the  $\text{Sm}^{3+}$  and  $\text{La}^{3+}$  sulfonates were thermally treated in the interval up to 1273 K (air flow) and their residues characterized through analysis of synchrotron high-resolution X-ray powder diffraction pattern (XRD) with Rietveld analysis to evaluate the oxysulfate/oxysulfide ( $\text{Ln}_2\text{O}_2\text{SO}_4/\text{Ln}_2\text{O}_2\text{S}$ ) phase contents. In this study, we investigate the occurrence of the  $\text{Sm}_2\text{O}_2\text{SO}_4/\text{Sm}_2\text{O}_2\text{S}$  phases in the  $\text{Sm}^{3+}$  sulfonate decomposition even though the  $\text{La}_2\text{O}_2\text{SO}_4$  phase prevails after the  $\text{La}^{3+}$  sulfonate is treated at 1273 K.

## Experimental procedure

### Synthesis procedure of the $\text{Sm}_2(\text{DAS})_6 \cdot 14\text{H}_2\text{O}$

The synthesis of the  $\text{Sm}^{3+}$  diphenylamine-4-sulfonate was successful with slow addition of solutions of  $\text{Sm}^{3+}$  sulfates hydrated to the water/ethyl alcohol solutions (7:1) containing Ba-DAS.  $\text{BaSO}_4$  precipitation occurred at a temperature of 343 K, under an inert atmosphere, in the absence of light and with constant agitation [9, 10].

A dark yellow product extremely soluble in water was obtained by filtration of impurities, concentration under vacuum, crystallization from and washing with purified hexane.

## Characterization

Carbon, hydrogen, and nitrogen contents of the sulfonate were determined using a Perkin Elmer 2400 (CHN) analyzer. Quantitative elemental analysis of  $\text{Sm}^{3+}$  was performed by EDTA complexometric titration. The IR spectrum was obtained with a Bomem MB 100 FTIR with operation range between 350 and 4000  $\text{cm}^{-1}$  in KBr beam splitters. Thermogravimetric analysis (TG/DTG) of the compound was carried out in a Shimadzu TGA-50H instrument, in a platinum crucible, under purified oxygen ( $\text{O}_2$ ) or nitrogen ( $\text{N}_2$ ) flows, at a 60  $\text{mL min}^{-1}$  flow rate, at a temperature range of 298–1273 K (heating rate of 278  $\text{K min}^{-1}$ ). XRD diffractograms of both decomposition residues were obtained in a HZG diffractometer equipped with a quartz monochromator for the radiation line  $\text{K}\alpha$  of Co ( $\lambda = 1.79020 \text{ \AA}$ ). The high-resolution X-ray powder diffraction (XRD) measurement was performed at the D10b-XPD beamline of the Synchrotron Light Laboratory (LNLS) using the wavelength  $\lambda = 2.0836 \text{ \AA}$ , at ambient pressure. A Ge (111) analyzer crystal was placed in a goniometer attached to the  $2\theta$  arm, and a scintillation detector was used. The Rietveld analysis was performed using the GSAS + EXPGUI suite [11–13]. The peak profile function was modeled using a convolution of the Thompson–Cox–Hastings pseudo-Voigt (pV-TCH) function14 with the asymmetry correction described by Finger et al. [15] to account for the asymmetry due to the beam axial divergence. In order to account for the anisotropy in the half width of the reflections, the bi-dimensional model described by Larson and Von Dreele [12] was used for crystallite size. For anisotropic strain, the model described by Stephens [16] was adopted.

## Results and conclusions

The formula  $\text{Sm}_2(\text{DAS})_6 \cdot 14\text{H}_2\text{O}$  (% Sm exp. = 14.90, % Sm theor. = 14.74; % C exp. = 42.15, % C theor. = 42.34; % N exp. = 3.90, % N theor. = 4.11; % H exp. = 4.03, % H theor. = 4.34; yield = 60.0%;  $M = 2040.72 \text{ g/mol}$ ) can be assigned to the reaction product. The TG/DTG curves of the  $\text{Sm}^{3+}$  diphenyl-4-amine sulfonate under  $\text{N}_2$  and  $\text{O}_2$  atmospheres are presented in Figure 1a, b. The behavior of the mass loss curves under both atmospheres is significantly different. The organic losses of the  $\text{Sm}^{3+}$  diphenyl-4-amine are fully complete under  $\text{O}_2$  at about 773 K (% residue = 25.08) (Fig. 1a), while at 1273 K under  $\text{N}_2$  the decomposition is still incomplete (% residue = 31.54) (Fig. 1b).

The  $\text{La}^{3+}$  sulfonate was obtained as described previously by using  $\text{Na}^+$  diphenyl-4-amine sulfonate ligand under the same conditions as the  $\text{Sm}^{3+}$  sulfonate, also

**Fig. 1** TG curves of  $\text{Sm}_2(\text{DAS})_3$  under (a)  $\text{N}_2$  and (b)  $\text{O}_2$  flows

characterized by TG/DTG, XRD and IR data [9]. However, unlike the  $\text{Sm}^{3+}$  sulfonate synthesized in this study, the TG/DTG data for the  $\text{La}^{3+}$  sulfonate indicate total decomposition at 1273 K under  $\text{N}_2$  (Fig. 2). The XRD of the TG residue of this compound was previously identified as the lanthanum oxide sulfate with molecular formula  $\text{La}_2\text{O}_2\text{SO}_4$ .

In another experiment, the  $\text{La}^{3+}$  and  $\text{Sm}^{3+}$  sulfonates were treated at 1273 K under air and both residues were then submitted to XRD analysis refined through Rietveld methodology, giving different proportions for the oxysulfate and oxysulfide phases (Table 1; Figs. 3, 4) [11–16]. The  $\text{La}^{3+}$  sulfonate residue contains the oxysulfate  $\text{La}_2\text{O}_2\text{SO}_4$  as the predominant phase (83%), the  $\text{LaO}_2\text{S}_2$  oxysulfide constitutes just a small part. Contrarily, the oxysulfide phase  $\text{Sm}_2\text{O}_2\text{S}_2$  (61%) prevails in the  $\text{Sm}^{3+}$  sulfonate residue.

In both experiments described earlier, the  $\text{La}^{3+}$  sulfonate seem to present, under the same conditions, a lesser

thermal stability than the  $\text{Sm}^{3+}$  sulfonate. Normally, the lanthanide ions form compounds whose properties vary gradually together with the decrease in radius of the metal ions of the series [1–5]. However, we consider that only this effect does not seem to be enough to produce a definitive change in the sulfonate properties [3, 6, 9, 10]. Additional data concerning this question are presented in the following paragraphs.

The  $\text{Sm}^{3+}$  and  $\text{La}^{3+}$  sulfonates were chemically synthesized by replacing the alkaline ions [9, 10]. Therefore, some modifications in the ligand arrangements around these metal ions, more highly charged than the alkaline ions, are expected [3, 9, 10]. Table 2 contains the IR frequency assignments for Ba, La, and Sm sulfonates [9, 10, 17–21]. The IR bands of the  $\text{Ba}^{2+}$  sulfonate at frequencies of 1597, 1511, 1496  $\text{cm}^{-1}$  are attributed to the stretching of C=C aromatic bonds in the ring. These bands were more numerous and intense in the presence of  $\text{Ln}^{3+}$  ions, that are more effective to promote the electronic

	844 <sub>(s)</sub>	843 <sub>(s)</sub>	831 <sub>(w)</sub>

delocalization into the diphenyl-4-amine rings. The extent of this effect can show a significant decrease in the  $1326 \text{ cm}^{-1}$  band C–N stretching. However, the torsion bands in and outside of plane of the C–H aromatic bands ( $1138$ ,  $1008$ , and  $843 \text{ cm}^{-1}$ ) remain unchanged, as well as the symmetrical bending ( $1377 \text{ cm}^{-1}$ ) [9, 10, 17, 18, 21].

The most significant values outlined in Table 2 refer, nevertheless, to the frequency characteristics of the interaction between the sulfonate group ( $\text{SO}_3^-$ ) and the lanthanide ions [9, 10, 17, 18, 21]. The  $1229$ ,  $1184$  and

$1051 \text{ cm}^{-1}$  bands of the  $\text{Ba}^{2+}$  sulfonates can usually be attributed to the asymmetric (doubly generated) and symmetric stretching of the sulfonate group with symmetry  $C_{3V}$ . As indicated, the  $1229 \text{ cm}^{-1}$  band is strongly diminished or not found in the  $\text{La}^{3+}$  and  $\text{Sm}^{3+}$  sulfonates. This effect is usually attributed to the decrease in the  $C_{3V}$  symmetry, which removes the double degeneracy of the asymmetric stretching, lowering the group symmetry to  $C_{2V}$  [10, 17, 18, 21]. Other two bands of the  $\text{Ba}^{2+}$  sulfonate group,  $1184$  and  $1051 \text{ cm}^{-1}$ , were displaced to frequencies of symmetric and asymmetric stretching of the group S=O [10, 17, 18, 21]. It was previously emphasized that the modifications in the  $\text{La}^{3+}$  and  $\text{Sm}^{3+}$  environments tend to be only a gradual ligand rearrangement. Therefore, it is reasonable to suppose that the smaller  $\text{Sm}^{3+}$  ion will accommodate more easily a smaller group such as the sulfoxide (S=O). This question was previously examined [2, 3, 9, 10, 22].

The oxysulfates  $\text{Ln}_2\text{O}_2\text{SO}_4$  ( $\text{Ln} = \text{La}, \text{Pr}$ ) structures have been described by Rietveld analysis. The powders were similar and indexed with monoclinic structure with  $C2/c$  space group. The crystal structure of La and Pr oxysulfates can be described as alternative stacking of a  $(\text{Ln}_2\text{O}_2)^{2+}$  layer along the a-axis interacting with the sulfate  $\text{SO}_4^{2-}$  or sulfide  $\text{S}^{2-}$  anions. The  $(\text{Ln}_2\text{O}_2)^{2+}$  layers consist of tetrahedron units connected by sharing of edges [2, 3]. Nevertheless, especially for the  $\text{La}^{3+}$  oxysulfate ( $\text{Ln}_2\text{O}_2\text{SO}_4$ ), the units of the  $\text{SO}_4^{2-}$  anion bonded to the  $(\text{La}_2\text{O}_2)^{2+}$  layers show O–S–O angles in the range  $104^\circ$ – $114^\circ$  suggesting a distortion from the typical  $T_d$  symmetry [2, 3]. For the  $\text{Pr}_2\text{O}_2\text{SO}_4$  structure, this distortion in the  $\text{SO}_4^{2-}$  anion symmetry is more obvious and the angles vary in the range  $103^\circ$ – $116^\circ$ . With an increase in the  $T_d$  distortion of  $\text{SO}_4^{2-}$  anion, sulfonate stability is expected to decrease. This effect is indicated as a possible structural reason for the lower reduction temperature, for the release of oxygen from  $\text{Pr}_2\text{O}_2\text{SO}_4$ , as well as for the unfavorable reoxidation of  $\text{Pr}_2\text{O}_2\text{S}$  to  $\text{Pr}_2\text{O}_2\text{SO}_4$  [2, 3].

phase are presented in Table 3. Both compounds can be indexed to the spatial groups  $P-3m1$  and the trigonal space group. The crystalline structure is also commonly described as alternative columns of  $(\text{Ln}_2\text{O}_2)^{2+}$  in the tetrahedral layers connected by sharing of the edges and interacting with the  $\text{S}^{2-}$  layers. Consequently, the phase transformation from  $\text{Ln}_2\text{O}_2\text{SO}_4$  to  $\text{Ln}_2\text{O}_2\text{S}$  has been considered as only involving the removal of ions surrounding sulfur as a consequence of the structural similarity between  $\text{Ln}_2\text{O}_2\text{SO}_4$  and  $\text{Ln}_2\text{O}_2\text{S}$  [2, 3]. This is considered reasonable since the differences in the Ln–O<sub>1</sub> distance values of the La (2.461 Å), Pr (2.39 Å), and Sm (2.405 Å) oxysulfides are not really large (Tables 4, 5; Figs. 5, 6). However, despite the similarity of these values, it refers only to the effects promoted in the  $(\text{Ln}_2\text{O}_2)^{2+}$  layers by the gradual decrease in the ionic radius in the lanthanide  $\text{Ln}^{3+}$  ions series [3].

Otherwise, it can be observed that the distances of La<sub>1</sub>–S<sub>1</sub> = 3.041 Å and Sm<sub>1</sub>–S<sub>1</sub> = 2.933 Å show significant differences which can really indicate an expressive intensification in the bond connecting the  $(\text{Sm}_2\text{O}_2)^{2+}$  layers and the  $\text{S}^{2-}$  sulfide ions.

Finally, we believe that the changes in bond characteristics along the lanthanide series could reflect on the stability of oxysulfates. The structural changes in the  $\text{La}^{3+}$  ions

**Fig. 5**  $\text{Sm}_2\text{O}_2\text{S}$  structure

symmetry when coordinated by sulfonate/oxysulfate are less hindered than during the conversion sulfonate into oxysulfide. Thus, the predominance of the  $\text{La}^{3+}$  oxysulfate over the oxysulfide phase, at 1273 K, results in a greater thermal stability for  $\text{La}^{3+}$  sulfonate. In practical terms, this behavior facilitates the understanding of the weak tendency to reduction shown by  $\text{La}^{3+}$  oxysulfate under  $\text{H}_2$  flow [1–3].

Therefore, since the  $\text{Sm}^{3+}$  ion is smaller than  $\text{La}^{3+}$ , this ion will react more easily with the  $\text{S}^{2-}$  ions (oxysulfide) than with  $\text{SO}_4^{2-}$  ions (oxysulfate) [2, 3, 9]. For this reason, the oxysulfide phase represents the highest percentage in the thermal residue of the  $\text{Sm}^{3+}$  sulfonate at 1273 K. The conversion capacity of the oxysulfate phase into

**Fig. 6**  $\text{La}_2\text{O}_2\text{S}$  structure

oxysulfide is associated with the accommodation facility of the  $\text{SO}_4^{2-}$  or  $\text{S}^{2-}$  anions by the  $(\text{Ln}_2\text{O}_2)^{2+}$  ( $\text{Ln} = \text{La}, \text{Sm}$ ) layer. Since there are favorable interactions between the  $\text{SO}_4^{2-}$  and  $\text{La}^{3+}$ , it would tend to remain as oxysulfate. On the contrary, the  $\text{Sm}^{3+}$  accommodations will be stabilized by interactions with the sulfide anion in the  $\text{C}_{2v}$  or  $\text{C}_s$  symmetries.

## Conclusions

The stability of lanthanide oxysulfides ( $\text{LnO}_2\text{S}$ ) can be accentuated along the lanthanide series due to maintenance of the 3+ charge for the smallest members. The net effect

of this charge is to promote the electronic displacement in the diphenyl-4-amine rings towards the oxygen bonded to the sulfur of the sulfonic group allowing the  $\text{S}^{6+}$  ions to be reduced to  $\text{S}^{2-}$  ions, leading to  $\text{Ln}_2\text{O}_2\text{S}$ . The distortion in the  $\text{SO}_4^{2-}$  group becomes stronger in the  $\text{Ln}_2\text{O}_2\text{SO}_4$  containing smaller and heavier members, such as  $\text{Sm}_2\text{O}_2\text{SO}_4$ , thus favoring the obtention of the  $\text{Sm}_2\text{O}_2\text{S}$  phase.

**Acknowledgements** We are especially grateful to the Brazilian Synchrotron Light Laboratory (LNLS) Campinas.
