## NOTES.

On the Determination of Fluorine.--When fluorine is determined by the Berzelius<sup>1</sup> method the results vary and are considerably too low. Seven determinations gave 76 to 94 per cent. fluorine as calcium fluoride. I repeated the work of Seeman<sup>2</sup> but without being able to find where the loss occurred. Fusing the fluoride with sodium peroxide in a nickle crucible gave no better results. Fourteen determinations, gave 81.4 to 94 per cent, of calcium fluoride taken. I am led to believe that some of the fluorine is retained in the fusion residues as a complex fluoride<sup>3</sup>. А. А. Косн. probably in combination with silica.

The Rapid Determination of Water in Butter. Aluminum Beaker Method.—In the November (1906) Journal,<sup>4</sup> I described a method for the rapid determination of water in butter, of sufficient accuracy for factory purposes, which consisted merely in boiling the water off from a weighed portion of butter contained in a wide test-tube heated by the naked flame of an alcohol lamp. Very shortly thereafter I made a seemingly slight modification in the method, by adopting the use of an aluminum beaker in place of the test-tube-a mere change in utensil, but a change which so greatly improves the method, both by facili-
