show that $\gamma_{\mathrm{Pb}^{++}}$is given fairly accurately by the Debye-Huickel expression in solutions of alkali chlorides up to $0.16 M$.

## Summary

Solubilities of $\mathrm{Pb}_{3}\left(\mathrm{PO}_{4}\right)_{2}$ and $\mathrm{PbHPO}_{4}$ in aqueous solutions have been measured, lead-ion activities being determined with the lead electrode. The values of the solubility products deduced are as follows: $S_{2}=a_{\mathrm{Pb}++} \times$ $a_{\mathrm{HPO}_{4}--}=10^{-9.90}$ at $25^{\circ} ; 10^{-9.62}$ at $37.5^{\circ}$. $S_{3}=a_{\mathrm{Pb}^{++}}^{3} \times a_{\mathrm{PO}_{4}---}^{2}=$ $10^{-42.10}$ at $25^{\circ}, 10^{-42.00}$ at $37.5^{\circ}$, when $K_{3}$ (the third ionization constant of phosphoric acid) is taken to have the values $10^{-12.30}$ at $25^{\circ}$ and $10^{-12.66}$ at $37.5^{\circ}$.

The conditions for equilibrium between the two salts are discussed and the biological bearing of the work is mentioned. $\mathrm{Pb}_{3}\left(\mathrm{PO}_{4}\right)_{2}$ is the more stable salt under body conditions.

## THE IONIZATION CONSTANTS OF PHOSPHORIC ACID ${ }^{1}$

By Maurice Jowett and Horace Millet<br>Recerved August 20, $1928 \quad$ Published April 5, 1929

In the course of an investigation ${ }^{2}$ on the solubilities of the secondary and tertiary phosphates of lead, it became evident that the values available in the literature for the ionization constants of phosphoric acid were insufficient for the purpose of that work.

We therefore have made measurements to determine the first ionization constant at 25 and $37.5^{\circ}$. A few measurements bearing on the second ionization constant are also reported. Relevant data of other observers are also considered and a value is derived for the third ionization constant. The activity concept is made use of throughout.

## Methods

Measurements of hydrogen-ion activity were made by means of cells in which a quinhydrone electrode was connected with a normal calomel electrode by a bridge of saturated potassium chloride solution. This bridge is assumed to eliminate liquid-liquid $P$. D's.

At $25^{\circ}$ the $P_{\mathrm{H}}$ is obtained by means of the relation ${ }^{3}$

$$
p \mathrm{H}^{+}=\frac{0.4136-E}{0.05911}
$$

[^0]where $E$, the e.m.f. of the cell, is positive when the quinhydrone electrode is the positive element.

The corresponding formula for $37.5^{\circ}$ is ${ }^{4}$

$$
p \mathrm{H}^{+}=\frac{0.4068-E}{0.06160}
$$

When the solutions have a high electrolyte concentration, a correction must be made for the so-called neutral salt error of the quinhydrone electrode. The corrections for an ionic strength of 0.16 have been taken by us as $\Delta p \mathrm{H}^{+}=-0.008$ at $25^{\circ 5}$ and $\Delta p \mathrm{H}^{+}=-0.006$ at $37.5^{\circ} .{ }^{6}$ The hydrogen electrode standard is that of G. N. Lewis, Brighton and Sebastian. ${ }^{7}$

The e.m.f. measurements were carried out in duplicate. Solutions were made up at room temperature from recrystallized salts. No correction has been made for the expansion of the solutions with rising temperature.

The First Ionization Constant.-The first ionization constant of phosphoric acid, $K_{1}$, is defined by the relation

$$
\begin{equation*}
p K_{1}=p \mathrm{H}^{+}+p \mathrm{H}_{2} \mathrm{PO}_{4}^{-}-p \mathrm{H}_{3} \mathrm{PO}_{4} \tag{1}
\end{equation*}
$$

where $p X$ denotes the negative logarithm of the activity of the chemical species $X$. It is also useful to define a quantity $K_{1}^{\prime}$ by the relation

$$
\begin{equation*}
p K_{1}^{\prime}=p \mathrm{H}^{+}+p C_{\mathrm{H}_{2} \mathrm{PO}_{4}}-p C_{\mathrm{H}_{3} \mathrm{PO} 4} \tag{2}
\end{equation*}
$$

where $p C_{X}$ denotes the negative logarithm of the concentration of the chemical species $X$.

Older work has not been calculated in terms of the activity concept, with the exception of the conductivity measurements of Noyes and Eastman at $18^{\circ}$ given by Abbott and Bray, ${ }^{8}$ which Sendroy and Hastings ${ }^{9}$ state to fit the relation

$$
p K_{1}^{\prime}=2.11-0.5 \sqrt{\mu}
$$

$\mu$ being the ionic strength.
The e.m.f. data of Ringer ${ }^{10}$ do not lead to a definite value for $p K_{1}$, when calculated according to activity theory.

Measurements in Dilute Solutions.-Solutions were made up by diluting mixtures of decimolar $\mathrm{KH}_{2} \mathrm{PO}_{4}$ and decinormal HCl . The stoichiometric composition of the solutions and the $P_{\mathrm{H}}$ values obtained are given in Table I.

[^1]TABLE I
Composition and $P_{\text {h }}$ Values of Dilute Solutions

| No. | Composition <br> $\mathrm{O}_{4}, \mathrm{M}$ HC1, $M$ <br> Temp., $25^{\circ}$ |  | $P_{\mathrm{H}}$ values <br> from quinhydrone elec. | No. | Composition <br> $\mathrm{KH}_{2} \mathrm{PO}_{4}, \mathrm{M} \quad \mathrm{HCl}, \mathrm{M}$ Temp., $37.5^{\circ}$ |  | $P_{\text {H }}$ values from quinhydrone elec |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | 0.015 | 0.005 | 2.703 | 6 | 0.01667 | 0.010 | 2.406 |
| 2 | . 0225 | . 0065 | 2.675 | 7 | . 0225 | . 0065 | 2.718 |
| 3 | . 030 | . 008 | 2.667 | 8 | . 025 | . 009 | 2.578 |
| 4 | . 045 | . 011 | 2.652 | 9 | . 0375 | . 0195 | 2.307 |
| 5 | . 061 | . 014 | 2.651 |  |  |  |  |

In order to calculate values of $p K_{1}$ from the above data, we must evaluate $\gamma_{\mathrm{H}^{+}}$and $\gamma_{\mathrm{H}_{2} \mathrm{PO}_{4}-}$, the activity coefficients of hydrogen ion and the primary phosphate ion. Since the solutions are not very concentrated, approximate relationships will be reasonably accurate.
According to Brönsted, ${ }^{11}$ in solutions of hydrochloric acid and potassium chloride up to 0.1 molar the following relations hold good

$$
\begin{aligned}
& -\log \gamma_{\mathrm{H}^{+}} \gamma_{\mathrm{Cl}^{-}}=0.90 \sqrt{\mu}-\mu \\
& -\log \gamma_{\mathrm{K}^{+}} \gamma_{\mathrm{Cl}^{-}}=\sqrt{\mu}-0.8 \mu
\end{aligned}
$$

Hence, assuming that $\gamma_{\mathbf{k}^{+}}=\gamma_{\mathrm{Cl}^{-}}$and that $\gamma_{\mathrm{Cl}^{-}}$is the same in corresponding solutions of potassium chloride and hydrochloric acid, we derive the equation

$$
\begin{equation*}
-\log \gamma_{\mathbf{H}^{+}}=0.4 \sqrt{\mu}-0.6 \mu \tag{3}
\end{equation*}
$$

which is assumed to hold for the present cases.
Cohn, ${ }^{12}$ working with mixtures of $\mathrm{KH}_{2} \mathrm{PO}_{4}$ and $\mathrm{K}_{2} \mathrm{HPO}_{4}$, was able to represent the activity coefficient of the primary phosphate ion by the relation

$$
\begin{equation*}
-\log \gamma_{\mathrm{H}_{2} \mathrm{PO}_{4}-}=\frac{0.5 \sqrt{\mu}}{1+1.5 \sqrt{\mu}} \tag{4}
\end{equation*}
$$

which we likewise take as valid for the systems we are considering.
From the $P_{\mathrm{H}}$ value, Equation 3 allows us to calculate $C_{\mathrm{H}^{+}}$, a value for $\mu$ being assumed and subsequently replaced by a more accurate one. $C_{\mathrm{H}_{2} \mathrm{PO}_{4}}$ - is then obtained from the principle of electrical equivalence $\left(C_{\mathrm{H}_{2} \mathrm{PO}_{4}}=C_{\mathrm{H}^{+}}+C_{\mathrm{K}^{+}}-C_{\mathrm{Cl}^{-}}\right)$, and $\mathrm{pH}_{2} \mathrm{PO}_{4}^{-}$calculated with the use of Equation 4. $C_{\mathrm{H}_{4} \mathrm{PO}}$, is obtained by subtracting $C_{\mathrm{H}_{2} \mathrm{PO}_{4}}$ from the total phosphate concentration. Up to the present point we have no basis for any value for $\gamma \mathrm{H}_{3} \mathrm{PO}_{4}$, which is left indeterminate.

Values of $p K_{1}-\log \gamma_{\mathrm{H}_{3} \mathrm{PO}}$, are calculated in Table II. To save space, values of $\gamma_{\mathrm{H}}{ }^{+}$and $\gamma_{\mathrm{H}_{2} \mathrm{PO}_{4}+}$ are omitted; they range from 0.908 to 0.866 , and 0.882 to 0.810 , respectively. The numbers refer to the solutions given in Table I.

The above values of $p K_{1}-\log \gamma_{\mathrm{H}_{3} \mathrm{PO}}$, show no trend with concentration and hence we take $\boldsymbol{\gamma}_{\mathrm{H}_{3} P O_{4}}=1$, and derive values for $p K_{1}$ at $25^{\circ}$ of 2.10 , and at $37.5^{\circ}$ of 2.16 .

Britton's data ${ }^{13}$ obtained by electrometric titration of phosphoric acid with caustic soda at $20^{\circ}$, using the hydrogen electrode, have been recalculated by us on the same basis as our own data, the mean value of $p K_{1}$ deduced being 2.01 . This is lower than the value 2.08 , which would be derived at $20^{\circ}$ from our values at 25 and $37.5^{\circ}$ if a constant temperature coefficient were assumed, and lower than the value calculated by Sendroy and Hastings for $18^{\circ}$, namely, 2.11.

Measurements at Total Ionic Strength 0.16.-For the purpose of the investigation already referred to, ${ }^{2}$ values of $p K_{1}^{\prime}$ at an ionic strength of 0.16 were required. Solutions of similar composition to those already used were made up, sodium chloride being added to raise the ionic strength to approximately 0.16.

Since no suitable value for $\gamma_{\mathrm{H}}+$ was available in the literature, $\gamma_{\mathrm{H}}+$ was measured for a solution containing $0.01 M \mathrm{HCl}$ and $0.15 M \mathrm{NaCl}$.

${ }^{13}$ Britton, J. Chem. Soc., 1927, 614.

The value found was 0.90 at $25^{\circ}$ and 0.91 at $37.5^{\circ}$, and this was taken as valid for the solutions of which the $P_{\mathrm{H}}$ was measured, the composition of which is given in Table III.
The value of $p K_{1}^{\prime}$ obtained is 1.94 at $25^{\circ}$ and 2.04 at $37.5^{\circ}$. The values of $p K_{1}, 2.11$ and 2.21, have been calculated from values of $\gamma_{\mathrm{H}_{2} \mathrm{PO}_{4}-}$ deduced elsewhere, ${ }^{2}$ namely 0.67 and 0.68 .
The agreement of these values of $p K_{1}$ with those obtained in more dilute solutions is sufficiently good to confirm the conclusion that $\gamma_{\mathrm{H}_{3} \mathrm{PO}}^{4}$ does not depart appreciably from a value of unity.

The Second Ionization Constant.-Many measurements have been made of the $P_{\mathrm{H}}$ values of mixtures of the primary and secondary alkali phosphates but the majority are unsuitable for the accurate evaluation of the second ionization constant of phosphoric acid, $K_{2}$, since the ionic strengths of the systems investigated are too high.
$K_{2}$ may be defined by the relation $p K_{2}=p \mathrm{H}^{+}+p \mathrm{H}_{2} \mathrm{PO}_{4}^{-}-p \mathrm{HPO}_{4}^{--}$ and the quantity $p K_{2}^{\prime}$ is defined similarly to $p K_{1}^{\prime}$.

Cohn ${ }^{12}$ has, however, recently made an extensive investigation of mixtures of primary and secondary phosphates at $18^{\circ}$, and this author's measurements, which are in concordance with those of Sörensen and Michaelis, lead to a value of $p K_{2}$ which is probably very accurate. Reduced to the G. N. Lewis standard for the hydrogen electrode, this value is 7.130 .

For other temperatures no values of any great accuracy appear to be available. Sendroy and Hastings ${ }^{9}$ state that unpublished measurements at $20^{\circ}$ give a value of about 7.18 , and suggest that the value at $38^{\circ}$ may be 7.15 .

We have made a number of measurements of the $P_{\mathrm{H}}$ of mixtures containing $0.0025 \mathrm{M} \mathrm{KH}_{2} \mathrm{PO}_{4}$ and $0.0025 \mathrm{Ma}_{2} \mathrm{HPO}_{4}(\mu=0.01)$. The mean values obtained are 6.997 at $25^{\circ}$ and 6.928 at $37.5^{\circ}$, probably accurate to about $0.003 \mathrm{pH} \mathrm{H}^{+}$. From these values, using Cohn's relation

$$
p K_{2}=p K_{2}^{\prime}+\frac{1.5 \sqrt{\mu}}{1+1.5 \sqrt{\mu}}
$$

$p K_{2}$ is calculated to be 7.127 at $25^{\circ}$ and 7.058 at $37.5^{\circ}$. The value at $25^{\circ}$ is close to the value 7.130 obtained by Cohn at $18^{\circ}$.

The data of Michaelis and Garmendia ${ }^{14}$ for the three most dilute solutions measured, when similarly calculated and reduced to the G. N. Lewis standard, give a value for $p K_{2}$ at $25^{\circ}$ of about 7.11. Britton's data ${ }^{13}$ on the same basis give a value of about 7.04 at $20^{\circ}$.

Measurements made by us on mixtures containing $0.0025 \mathrm{M} \mathrm{KH}_{2} \mathrm{PO}_{4}$ and $0.0025 \mathrm{M} \mathrm{Na}_{2} \mathrm{HPO}_{4}$, of which the ionic strength was raised to 0.16 with NaCl , gave $p \mathrm{H}^{+}$(and also $p \mathrm{~K}^{\prime}$ ) values of 6.680 at $25^{\circ}$ and 6.589 at $37.5^{\circ}$.
${ }^{14}$ Michaelis and Garmendia, Biochem. Z., 67, 431 (1914).

The Third Ionization Constant.-Sendroy and Hastings ${ }^{9}$ have made $P_{\mathrm{H}}$ measurements at $38^{\circ}$ on mixtures of secondary and tertiary phosphates and found that $p K_{3}^{\prime}$ could be represented approximately by the relation

$$
p K_{3}^{\prime}=12.66-2.25 \sqrt{\mu}
$$

$p K_{3}$ and $p K_{3}^{\prime}$ are defined in a manner similar to $p K_{1}$ and $p K_{1}^{\prime}$. As the data used lie between the limits $\sqrt{\mu}=0.25$ and $\sqrt{\mu}=0.50$, the extrapolation to infinite dilution is somewhat uncertain.
Suitable data for the calculation of $p K_{3}$ at other temperatures are scanty. Prideaux and Ward's measurements ${ }^{15}$ were made at ionic strengths of 0.085 upward. Kolthoff's measurements ${ }^{16}$ were also made at high ionic strengths; by a method not clearly explained this author calculates $p K_{3}$ at $18^{\circ}$ to be about 12.30 .

The electrometric titrations of Britton ${ }^{13}$ at $20^{\circ}$, however, were carried out in the range $\mu=0.033$ to $\mu=0.047$, and the values obtained may be used in attempting to evaluate $p K_{3}$.
No very satisfactory basis is available for calculating the required activity coefficients- $\gamma_{\mathrm{OH}^{-},} \gamma_{\mathrm{H}_{2} \mathrm{PO}_{4}--}$ and $\gamma_{\mathrm{PO}_{4}---}$

As an approximate relation we have made use of an equation analogous to that used by Sendroy and Hastings

$$
-\log \gamma=0.45 n^{2} \sqrt{\mu}
$$

$K_{w}$ has been taken as $0.68 \times 10^{-14}$. To Britton's $P_{\mathrm{H}}$ values 0.04 has been added to correct them to the G. N. Lewis standard.

Then $p K_{3}$ is defined by the relation

$$
p K_{3}=p \mathrm{H}^{+}+p C_{\mathrm{PO}_{4}---}-p C_{\mathrm{HzPO}_{4}-}+2.25 \sqrt{\mu}
$$

From $P_{\mathrm{H}}$ and $\gamma_{\mathrm{OH}}-, C_{\mathrm{OH}}-$ is evaluated, and $C_{\mathrm{PO}_{4}}--$ and $C_{\mathrm{H}_{2} \mathrm{PO}_{4}--}$ obtained from the principle of electrical equivalence.

Values at either end of the series have been omitted as being less accurate. The mean value of $p K_{3}$ obtained is 12.11 . It should be noted that Britton's data give values for $p K_{1}$ and $p K_{2}$ about 0.1 lower than do other data. An additional error of the same order may be introduced into $p K_{3}$ owing to our having used a tentative formula for the activity coefficients. Thus the value 12.11 may be in error by $0.1-0.2$. Sendroy and Hastings' value of 12.66 at $38^{\circ}$ may be in error to a similar extent. Thus the temperature coefficient is a doubtful quantity, but a value of 12.3 might be interpolated for $25^{\circ}$.

Heats of Ionization of Phosphoric Acid.-The heats of ionization of phosphoric acid, as far as the first two stages are concerned, may be calculated as follows from the values of $p K_{1}$ and $p K_{2}$ obtained in this paper.
${ }^{15}$ Prideaux and Ward, J. Chem. Soc., 125, 429 (1924).
${ }^{16}$ I. M. Kolthoff, Rec. trav. chim., 46, 350 (1927).

| Reaction | $\ddagger K\left(25^{\circ}\right)$ | $p K\left(37.5^{\circ}\right)$ | Heat evolved |
| :---: | :---: | :---: | :---: |
| $\mathrm{H}_{3} \mathrm{PO}_{4} \longrightarrow \mathrm{H}^{+}+\mathrm{H}_{2} \mathrm{PO}_{4}^{-}$ | 2.10 | 2.16 | +2000 |
| $\mathrm{H}_{2} \mathrm{PO}_{4} \longrightarrow \mathrm{H}^{+}+\mathrm{HPO}_{4}^{--}$ | 7.127 | 7.058 | -2300 |

The calculated heats of ionization, which are in calories per mole, refer, of course, to the ionization at infinite dilution.

The values of $p K_{3}$ calculated are insufficiently accurate for the heat effect of the third ionization step to be calculated. Heat, however, is evolved in this ionization.

## Summary

With the quinhydrone electrode measurements of the $P_{H}$ values of phosphate mixtures have been made which lead to the following values for the ionization constants of phosphoric acid

$$
\begin{aligned}
& p K_{1}\left(25^{\circ}\right)=2.10, \quad p K_{1}\left(37.5^{\circ}\right)=2.16 \\
& p K_{2}\left(25^{\circ}\right)=7.13, \quad p K_{2}\left(37.5^{\circ}\right)=7.06
\end{aligned}
$$

These figures are compared with those derived from other data.
From the data of Britton $p K_{3}$ at $20^{\circ}$ is calculated to be about 12.1.

# THE PRINCIPLES DETERMINING THE STRUCTURE OF COMPLEX IONIC CRYSTALS 

By Linus Pauling<br>Recervel September 5, 1928<br>Published April 5, 1929

1. The Relative Stability of Alternative Structures of Ionic Crystals.The elucidation of the factors determining the relative stability of alternative crystalline structures of a substance would be of the greatest significance in the development of the theory of the solid state. Why, for example, do some of the alkali halides crystallize with the sodium chloride structure and some with the cesium chloride structure? Why does titanium dioxide under different conditions assume the different structures of rutile, brookite and anatase? Why does aluminum fluosilicate, $\mathrm{Al}_{2} \mathrm{SiO}_{4}$ $\mathrm{F}_{2}$, crystallize with the structure of topaz and not with some other structure? These questions are answered formally by the statement that in each case the structure with the minimum free energy is stable. This answer, however, is not satisfying; what is desired in our atomistic and quantum theoretical era is the explanation of this minimum free energy in terms of atoms or ions and their properties.

Efforts to provide such a treatment for simple alternative structures, such as the sodium chloride and cesium chloride structures and the fluoride and rutile structures, have been made with the aid of the Born potential expression and modifications of it. Assuming that all ions repel each
