specific heat associated with electronic transitions in crystals. For our particular example, we determined the heat capacities of $\mathrm{Sm}_{2}\left(\mathrm{SO}_{4}\right)_{3}$. $8 \mathrm{H}_{2} \mathrm{O}$ at temperatures from 17 to $295^{\circ} \mathrm{K}$., and the data are reported here. These are compared with the heat capacities of $\mathrm{Gd}_{2}\left(\mathrm{SO}_{4}\right)_{3} \cdot 8 \mathrm{H}_{2} \mathrm{O}$ over the same temperature range. ${ }^{15}$ The quantitative agreement between the observed and computed
electronic specific heats is found satisfactory. ${ }^{28}$ The statistical weights for the levels in the basic multiplet were found to be equal to each other.
(28) The computations employed the energy intervals derived from the absorption spectra of $\mathrm{Sm}_{2}\left(\mathrm{SO}_{4}\right)_{r} \cdot 8 \mathrm{H}_{2} \mathrm{O}$ by Dr. F. H. Spedding and Dr. Richard Bear. The intervals were kindly furnished us before publication.

The Heat Capacity of $\mathrm{Gd}_{2}\left(\mathrm{SO}_{4}\right)_{3} \cdot 8 \mathrm{H}_{2} \mathrm{O}$ from 16 to $300^{\circ}$ Absolute

By J. Elston Ahlberg and Chester W. Clark

In the treatment of the electronic specific heat of samarium ion $\mathrm{Sm}^{+++}$considered in the preceding article ${ }^{1}$ it was necessary to use the differences in the heat capacities of $\mathrm{Sm}_{2}\left(\mathrm{SO}_{4}\right)_{3}$. $8 \mathrm{H}_{2} \mathrm{O}$ and $\mathrm{Cd}_{2}\left(\mathrm{SO}_{4}\right)_{3} \cdot 8 \mathrm{H}_{2} \mathrm{O}$. The heat capacity of $\mathrm{Gd}_{2}\left(\mathrm{SO}_{4}\right)_{3} \cdot 8 \mathrm{H}_{2} \mathrm{O}$ has been determined previously in this Laboratory by Giauque and Clark. ${ }^{2}$ Giauque and Clark suggested that for purposes other than those with which they were immediately concerned, it would be advisable to make a redetermination of the heat capacity of this salt. For reasons which Giauque and Clark ${ }^{2}$ have already pointed out, the particular calorimeter employed by them was unsatisfactory and was discarded after having been used only for their measurements on $\mathrm{Gd}_{2}\left(\mathrm{SO}_{4}\right)_{3}$. $8 \mathrm{H}_{2} \mathrm{O}$. For the purpose of comparison accuracy is gained by the measurement of the heat capacity of the two salts under as nearly identical conditions as possible.

Material.-The same sample of $\mathrm{Gd}_{2}\left(\mathrm{SO}_{4}\right)_{3} \cdot 8 \mathrm{H}_{2} \mathrm{O}$ as used by Giauque and Clark was employed for this series of measurements. Analysis furnished by Welsbach Company, Gloucester, New Jersey, showed this sample to be Gd $98.5 \%$, $\mathrm{Sm} 0.5 \%, \mathrm{~Tb} 1.0 \%$. The presence of these impurities, since they are so very similar in many

the points represents the heat capacity from 30 to $300^{\circ} \mathrm{K}$. to within a few tenths of a per cent. From 16 to $30^{\circ} \mathrm{K}$. the points are probably accurate to no more than a few per cent, due to the falling off of the temperature coefficient of gold resistance thermometers. In Fig. 1 the values of Giauque and Clark are indicated by circles and those of this research by solid black dots. It is evident that the results of Giauque and Clark show excellent agreement with this research from 16 to $200^{\circ} \mathrm{K}$. Divergence does occur between 200 and $300^{\circ} \mathrm{K}$. where the heat exchange corrections mentioned above become appreciable. The results of this research are given in Table I.

The experimental work reported here was performed in the Chemical Laboratory of the University of California. The calculations involved were in great part completed at The Johns Hopkins University

## Summary

The specific heat of $\mathrm{Gd}_{2}\left(\mathrm{SO}_{4}\right)_{3} \cdot 8 \mathrm{H}_{2} \mathrm{O}$ has been determined from 16 to $300^{\circ}$ Absolute.

# The Identity of Fermi's Reactions of Element 93 with Element 91 

By A. V. Grosse and M. S. Agruss

## Introduction

The interesting experiments recently performed by E. Fermi and his collaborators, ${ }^{1}$ on the bombardment of uranium with neutrons, have led him to conclude that elements with an atomic number above 92 are formed. He specifically assumes that his product, with a period of thirteen minutes, which is precipitated from a highly oxidizing and acid solution together with manganese, is the highest homolog of the latter or element 93 ; furthermore, in a later paper ${ }^{1 b}$ he assumes that his product with a period of ninety to one hundred minutes, which is partially ( $50-60 \%$ ) precipitated with rhenium sulfide from a highly acid solution, is isotopic with the thirteen minute product.

[^0]However, since we have to expect, according to the periodic law, other properties ${ }^{2}$ for the highest homolog of manganese, we have repeated Fermi's chemical experiments, using protactinium, the longest lived isotope of element 91, as an indicator and obtained results described below.

## Materials and Procedure

Materials.-The following solutions were prepared, using C. P. grade of chemicals in all cases: (1) a water solution of uranyl nitrate containing 2.763 g . of $\mathrm{U}_{3} \mathrm{O}_{8}$ per 50 cc.; (2) a manganese nitrate solution containing 0.1179 g. of $\mathrm{MnO}_{2}$ per 10 cc .; (3) a $15 \%$ solution of sodium thiosulfate; (4) a water solution of potassium perrhenate containing 0.1609 g . of $\mathrm{KReO}_{4}$ per 25 cc ; (5) a $4 \%$ sulfuric acid solution of protactinium pentoxide, equivalent to $900 \mathrm{U}_{3} \mathrm{O}_{3}$ units of pure protactinium ${ }^{3}$ per 5 cc ., and containing also 5 mg . of ferric oxide in 5 cc .
