# Ammonia. The Heat Capacity and Vapor Pressure of Solid and Liquid. Heat of Vaporization. The Entropy Values from Thermal and Spectroscopic Data 

By Roy Overstreet and W. F. Giauque

In a former communication, Giauque, Blue and Overstreet ${ }^{1}$ showed that the existing low temperature calorimetric data on ammonia lead to an entropy value about one cal./deg. per mole greater than the value obtained from band spectrum observations. The purpose of this research has been to obtain accurate calorimetric data in the hope of eliminating the discrepancy. As was expected, the inconsistency was found to be due chiefly to the inaccuracy of the existing calorimetric data.

Preparation of Ammonia.-The ammonia used in this investigation was prepared by the action of a saturated solution of potassium hydroxide on C. P. ammonium chloride. The gas was subjected to a preliminary drying by conducting it slowly through a vertical glass column, approximately one meter in length, containing broken sticks of potassium hydroxide. The ammonia issuing from the column was condensed over sodium in one of a series of glass distillation bulbs by means of solid carbon dioxide in ether. Approximately 250 cc . of liquid was prepared in this manner. After standing over sodium for twelve hours, the substance was then distilled five times. In each case the first 10 cc . of distillate and the final 10 cc . portion was discarded. Following each distillation, the gas was cooled to the temperature of liquid air and the line was evacuated to $10^{-5} \mathrm{~mm}$.

The amount of liquid-soluble solid-insoluble impurity was estimated to be not more than one mole in one hundred thousand. This estimate was made on the assumption that the slight rise in heat capacity below the melting point was due to premelting. The single high observation given later in Table IV was confirmed by several measurements, not included, over smaller temperature intervals just below the melting point.

Apparatus.-The measurements were carried out in Gold Calorimeter II $^{2}$ which was rebuilt and described by Blue and Giauque. ${ }^{3}$ A full description of a calorimeter of this type has been given by Giauque and Egan. ${ }^{4}$

The temperature scale was obtained from the copperconstantan thermocouple of laboratory designation "W.". The thermocouple, which was originally compared with a hydrogen gas thermometer, has been compared frequently with the oxygen and hydrogen vapor pressure thermometers. The latest comparison, made after the completion of this work, gave the following corrections to be added to the original calibration made nine years before: $0.01^{\circ}$ at the

[^0]boiling point of oxygen, $90.13^{\circ} \mathrm{K}$., $0.11^{\circ}$ at the melting point of oxygen, $54.39^{\circ} \mathrm{K}$., $0.13^{\circ}$ at the $43.76^{\circ} \mathrm{K}$. transition of oxygen, $0.15^{\circ}$ at the boiling point of hydrogen $20.37^{\circ} \mathrm{K}$. and $0.17^{\circ}$ at the triple point of hydrogen, $13.95^{\circ}$ K . These corrections were employed in the temperature scale used in this research. The gold resistance ther-mometer-heater, used for greater calorimetric precision and accuracy, was calibrated continuously during the measurements by comparison with the thermocouple.

The Vapor Pressure of Ammonia.-The vapor pressure was determined by means of a manometer which could be connected directly with the calorimeter. A cathetometer was used as a comparison instrument with a standard meter mounted in the manometer case. The vapor pressure observations on solid ammonia from $176.92^{\circ} \mathrm{K}$. to the melting point, $195.36^{\circ} \mathrm{K}$., have been represented by the equation
$\log _{10} P$ (int. $\mathrm{em} . \mathrm{Hg}$ ) $=-1630.700 / T+9.00593$
For liquid ammonia from 199.26 to $241.59^{\circ} \mathrm{K}$.

$$
\begin{aligned}
\log _{10} P \text { (int. cm. Hg) }= & -1612.500 / T-0.012311 T+ \\
& 0.000012521 T^{2}+10.83997
\end{aligned}
$$

In Table I the observed values are compared with those given by equations 1 and 2 . The pressure observations are corrected to international centimeters of mercury by means of data given in the "I.C.T." 6 The standard acceleration of gravity was taken as $980.665 \mathrm{~cm} . / \mathrm{sec}^{2}{ }^{2}$. The gravitational acceleration, $979.973 \mathrm{~cm} . / \mathrm{sec} .^{2}$ has been determined for this location by Sternewarte. ${ }^{7}$ Because of the high relative accuracy, which could be obtained with the resistance thermometer, the temperatures for the liquid are given to $0.001^{\circ}$. The absolute error may be as high as several hundredths of a degree.
From equation 2 the boiling point was calculated to be $239.68^{\circ} \mathrm{K}$.

The deviations given in the third column of Table I were calculated by assuming that the temperature observations were correct. The deviations given in the fourth column of the table were calculated assuming that the pressures were correct.

A summary of observations on the melting point temperature is given in Table II. Observation 1 was a single determination. Observations 2 and 3 were taken consecutively over a period of about two hours. Observations 4,5 and 6 were taken consecutively over a period of approximately five hours. Table III contains a summary of the more recent determinations of the melting and boiling points of ammonia.

Keyes and Brownlee ${ }^{8}$ (1918)
Cragoe, Meyers and Taylor ${ }^{9}$ (1920)
Henning and Stock ${ }^{10}$ (1921)
Eucken and Karwat ${ }^{11}$ (1924)
$195.36 \quad 239.68$ This research
As may be seen from Table III the melting and boiling point temperatutes agree fairly well with

[^2]those obtained by Cragoe, Meyers and Taylor ${ }^{9}$ and by Henning and Stock. ${ }^{10}$ The latter authors did not make observations at the melting point but by substituting the observed triple point pressure in their vapor pressure equation the value $195.39^{\circ} \mathrm{K}$. is found as compared to the present observation of $195.36^{\circ} \mathrm{K}$,

The present value obtained for the boiling point is $0.07^{\circ}$ below that of Cragoe, Meyers and Taylor and $0.06^{\circ}$ below that of Henning and Stock.

The agreement is perhaps all that can be expected when one considers the possible errors of the several experimenters. The gas thermometer scale calibration by Giauque, Buffington and Schulze, ${ }^{5 a}$ of the thermocouple used in the present work, was estimated by those authors to be accurate to $\pm 0.05^{\circ}$. However, high relative accuracy was obtained by means of the resistance thermometer which was read with a scale giving about $10^{4} \mathrm{~mm}$. per degree. The resistance thermometer was calibrated by comparison with the thermocouple at frequent intervals over a wide temperature range.

The value, 4.558 cm ., given for the triple point pressure is in good agrecment with an observation of Bergstrom ${ }^{11 \mathrm{a}}$ who obtained 4.55 cm . Also by putting the melting point observation of the present research in the vapor pressure equation of Henning and Stock one obtains the value 4.55 cm . The observation, 4.49 cm , of Cragoe, Meyers and Taylor is evidently in error. Putting their value for the melting point, $195.40^{\circ} \mathrm{K}$., into their vapor pressure equation one obtains 4.53 cm .

The Heat Capacity of Ammonia, -The heat capacity results are given in Table IV, For the calculation of energy, 1.0004 absolute joules were taken equal to 1 international joule and 4.185 absolute joules were taken equal to 1 calorie. The data are shown in Fig. 1. The heat capacity of ammonia has been measured by Eucken and Karwat ${ }^{11}$ and by Clusius, Hiller and Vaughen. ${ }^{12}$ In Table $V$ are recorded heat capacity values picked from a smooth curve through the observations. Since Eucken and Karwat have prepared a similar table, deviations from their data are included. Deviations from the data of Clusius, Hiller and Vaughen are not included, since their investigations were carried out, for the most part, at temperatures below $20^{\circ} \mathrm{K}$. However, their data at higher temperatures are too high by

Heat of Fusion,-Determinations of the heat of fusion of ammonia are given in Table VI. With the temperature slightly below the melting point, heat was added until all of the substance
was melted and the liquid heated slightly above the melting point. Correction was made for the $\int C_{p} \mathrm{~d} T$ and the premelting effect, It is interesting to compare the value for the heat of fusion obtained in this research with that calculated by Eucken and Donath ${ }^{13}$ from measurements of the heat of sublimation and heat of vaporization near the melting point, By a small extrapolation of their heat of condensation measurements, they have calculated the difference between the heat of sublimation and the heat of vaporization at the melting point to be $1380 \pm 8$ cal. Considering the large quantities of heat dealt with, the agreement between their value and the value of this research is good.

Table VI
Heat of Fusion of Ammonia

Heat of Vaporization.-The heat of vaporization was measured by adding energy and determining the amount of gas evolved. The ammonia was vaporized against a constant pressure, which was slightly above atmospheric pressure. A small correction was applied to obtain the value corresponding to 760 mm . A summary of the data is given in Table VII. Osborne and Van Dusen ${ }^{14}$ have measured the heat of vaporization of ammonia through the range -42 to $+52^{\circ}$. The value 5573 interpolated from their data is in excellent agreement with the value obtained in this research.
It has been of interest to calculate the heat of fusion and the heat of vaporization from the vapor pressure data. This has been done by assuming that Berthelot's equation of state can be used to correct for gas imperfection. The values are included in Tables VI and VII. The agreement with the experimental values is sufficiently close to justify the use of Berthelot's equation for the calculation of the entropy correction for the actual to the ideal gas states.

[^3]

| Mean 5581 |  |  |
| Osborne and Van Dusen 5573 |  |  |
| From vapor pressure equation 2, assuming a Berthelot gas |  |  |

Measurement of Amount of Ammonia.-All amounts were measured gravimetrically. The gas vaporized during the heat of vaporization runs was absorbed in 6 N sulfuric acid and weighed. The absorption bulbs were of $110-\mathrm{cc}$. capacity. All necessary precautions were taken to avoid loss of moisture from the bulb to the outside or the gain of moisture in the bulb from the outside. Following the heat of vaporization runs, the remainder was absorbed in a large absorption bulb
( 800 cc .) containing 6 N sulfuric acid and weighed. The small amount of gas remaining in the apparatus was calculated from the pressure and volume.

The Entropy from Calorimetric Data.-The entropy was calculated by graphical integration of $\int_{0}^{T} C_{p} \mathrm{~d} \ln T$ plus the entropies of fusion and vaporization. The entropy correction for gas imperfection was made using Berthelot's equation of state and the thermodynamic equation

$$
\begin{gathered}
\left(\frac{\partial S}{\partial P}\right)_{r}=-\left(\frac{\partial V}{\partial T}\right)_{P} \quad \text { from which } \\
\Delta S=S_{\text {ideal }}-S_{\text {sotuas }}=27 R T_{\mathrm{c}}{ }^{3} P / 32 T^{3} P_{\mathrm{o}} \\
T_{\mathrm{c}}=406.0^{\circ} \mathrm{K} \cdot{ }^{15} \text { and } P_{\mathrm{c}}=112.3 \text { atmospheres }{ }^{15}
\end{gathered}
$$

Then $\Delta S=0.07$ e. u. at the boiling point of ammonia. The entropy calculation is summarized in Table VIII.

The Entropy of Ammonia from Spectroscopic Data,-The translational entropy of ammonia was obtained from the Sackur-Tetrode equation
$S_{T}=3 / 2 R \ln M+5 / 2 R \ln T-R \ln P+5 / 2 R+$

$$
R \ln (2 \pi k)^{3 / 2} / h^{3} N^{3 / 2}+R \ln R \quad \text { (3) }
$$

$=3 / 2 R \ln M+5 / 2 R \ln T-R \ln P+4.967-16.024+$

| Entropy of actual gas at boiling point | $44.06 \pm 0.10 \mathrm{cal} . /$ deg. per mole |
| Correction for gas imperfection | 0.07 |
| Entropy of ideal gas at boiling point | 44.13 |

$R=1.9869$ cal./deg. per mole. The values of all natural constants are those given in the "I. C. T." ${ }^{\prime \prime}$ The remaining entropy was evaluated by means of the equation

$$
\begin{equation*}
S=R \ln Q+R T \mathrm{~d} \ln Q / \mathrm{d} T \tag{5}
\end{equation*}
$$

where $Q=p e^{-\epsilon / k T}$ summed over all states. $p$ is the $a$ priori probability and $\epsilon$ the energy of the state. For the rotational entropy the approximation

$$
\begin{equation*}
Q_{R}=\frac{1}{\sigma} \times \frac{8 \pi^{2}}{h^{3}} \times(2 \pi k T)^{8 / 2}\left(I_{1} I_{2} I_{3}\right)^{1 / 2} \tag{6}
\end{equation*}
$$

was used, where $\sigma$ is the symmetry number and $I_{1}, I_{2}$ and $I_{3}$ are the principal moments of inertia. Therefore
$S_{R}=R / 2 \ln I_{1} I_{2} I_{3}+3 / 2 R \ln T+R \ln \frac{8 \pi^{2}}{h^{3}} \cdot(2 \pi k)^{3 / 2}+$ $3 / 2 R-R \ln \sigma \quad(7)$
$=R / 2 \ln I_{1} I_{2} I_{3}+3 / 2 R \ln T-R \ln \sigma+267.65 \quad$ (8)
The moments of inertia have been taken from the observations of Wright and Randall ${ }^{16}$ on the pure rotation spectrum of ammonia. Since the molecule is a symmetrical top

$$
\begin{aligned}
& I_{1}=I_{2}=2.782 \times 10^{-40} \mathrm{~g} . \mathrm{cm} .^{2} \\
& I_{3}=4.33 \times 10^{-40} \mathrm{~g} . \mathrm{cm} .
\end{aligned}
$$

The vibrational entropy was calculated by means of equation 5. Ammonia has four normal vibrational frequencies. $v_{2}$ and $v_{4}$ have double a priori weights. $v_{1}$ and $v_{3}$ are single. $v_{1}=3335$ $\mathrm{cm} .^{-117} \nu_{3}=948 \mathrm{~cm} .^{-118} v_{4}=1631 \mathrm{~cm} .^{-117} v_{2}$ has never been observed spectroscopically. However, since it is known to be the largest frequency and does not contribute to the entropy below $298.1^{\circ} \mathrm{K}$., an estimate of Howard ${ }^{19} v_{2}=3450$ $\mathrm{cm} .^{-1}$ was assumed.

From the above equations and data the entropy of the ideal gas at the boiling point was calculated to be $44.10 \mathrm{cal} . / \mathrm{deg}$. per mole. The

(18) Barker, personal communication to Wright and Randall.
(19) Howard, J. Chem. Phys., 3, 207 (1935).
contribution due to vibration was only 0.05 cal./ deg. per mole. The value at $298.1^{\circ} \mathrm{K}$. was found to be 45.91 cal./deg. per mole. These values are compared with the experimental results in Table IX.

In making the above calculations the nuclear spin entropy has been ignored. Since the hydrogen atom has a spin of $1 / 2$ and nitrogen a spin of 1 unit, the amount $R \ln 24=6.31 \mathrm{cal} . / \mathrm{deg}$. per mole must be added to obtain the absolute entropy which has been included in Table IX for the sake of completeness. The values which do not include the nuclear spin contribution are the ones which should be used in ordinary thermodynamic calculations or compared with experimental values obtained from the ordinary application of the third law of thermodynamics.

Table IX
Comparison of Experimental and Spectroscopic Entropy Values of Ammonia

| T, ${ }^{\circ} \mathrm{K}$. |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  | Absolute | Less nuclear <br> spin entropy | Actual | Corrected to ideal state |
| 239.68 | 50.41 | 44.10 | 44.06 | 44.13 |
| 298.1 | 52.22 | 45.91 |  | 45.94 |

As may be seen from Table IX the value obtained from the third law of thermodynamics is in excellent agreement with that obtained with the assistance of spectroscopic data.

Lewis and Randal1 ${ }^{20}$ have given an equation for the free energy change in the reaction

$$
1 / 2 \mathrm{~N}_{2}+3 / 2 \mathrm{H}_{2}=\mathrm{NH}_{8}(\mathrm{~g})
$$

By means of this equation and the known entropies of nitrogen, $\mathrm{N}_{2}, S_{298.1}=45.79^{21}$ and hydrogen, $\mathrm{H}_{2}, S_{288.1}=31.23^{22}$ a value of $46.0 \mathrm{cal} . / \mathrm{deg}$. per mole is obtained for the entropy of ammonia at $298.1^{\circ} \mathrm{K}$. This value is in excellent agreement with the experimental value $45.94 \mathrm{cal} . / \mathrm{deg}$. per mole.

We thank Dr. C. C. Stephenson for assisting with the measurements and many of the calculations.

## Summary

The heat capacity of solid and liquid ammonia has been determined over their respective ranges from $15^{\circ} \mathrm{K}$. to the boiling point. The melting and boiling points were found to be 195.36 and $239.68^{\circ} \mathrm{K}$., respectively.

[^4]The heat of fusion is 1351.6 cal./mole. The heat of vaporization at the boiling point is 5581 . cal./mole.

The vapor pressure of solid and liquid ammonia has been measured and the data have been represented by the equations: solid ammonia 176.92 to $195.36^{\circ} \mathrm{K} . \log _{10} P$ (int. cm, Hg ) $=1630.700 / T$ +9.00593 ; liquid ammonia 199.26 to $241.59^{\circ} \mathrm{K}$. $\log _{10} P$ (int. cm. Hg ) $=-1612.500 / T-0.012311$ $T+0.000012521 T^{2}+10.83997$.
The molal entropy of the gas at the boiling point has been calculated by means of the third
law of thermodynamics and the experimental data. The value found, $44.13 \pm 10 \mathrm{e}, \mathrm{u}$. , is in excellent agreement with the value $44.10 \mathrm{e}, \mathrm{u}$. calculated from spectroscopic data.

From band spectrum data the entropy of ammonia at $298.1^{\circ} \mathrm{K}$. and 1 atmosphere was calculated to be $45.91 \mathrm{cal} . /$ deg. per mole.

The above entropy value, which should be used in ordinary thermodynamic calculations, does not include the nuclear spin entropy. The absolute entropy is 52.22 cal./deg. per mole.

## The Relative Atomic Weight of Oxygen from Air and Water Determined by an Interchange Reaction

By Thomas O. Jones and Norris F. Hall

An important difference in the composition of oxygen from the air and from water has been brought to light recently both in America and in Japan, ${ }^{1}$ and this has been confirmed subsequently ${ }^{2}$ by others. Various somewhat questionable assumptions and methods incident to the earlier papers have been discussed by Smith and Matheson, ${ }^{2}$ but there seems little doubt of the reality of the difference, which readily accounts for certain otherwise unexplained results of workers other than the discoverers. ${ }^{3}$ All of the results referred to above were obtained by burning elementary hydrogen with different sorts of oxygen, and electrolytic methods were generally employed to produce one or both of the gases.

We have now demonstrated this important effect by a method which involves neither electrolysis nor combustion, and which may prove practical for the preparation of large quantities of water abnormal as to its $\mathrm{O}^{18}$ content. The equilibrium between water and oxygen

$$
2 \mathrm{H}_{2} \mathrm{O}^{16}+\mathrm{O}_{2}^{18}=2 \mathrm{H}_{2} \mathrm{O}^{18}+\mathrm{O}_{2}^{18}
$$

if established at low temperatures would, according to Dole, ${ }^{18}$ account for the observed difference. On the other hand, it is found, using the methods
(1) (a) Dole, This Journal, 57, 2731 (1935); J. Chem. Phys., 4, 268, 1936 (6 $\gamma$ ); (b) Morita and Titani, Bull. Chem. Soc. Japan, 11, 36, 414 (1936) ( $7 \gamma$ ).
(2) (a) Greene and Voskuyl, This Journal, 58, 693 (1936) ( $6 \gamma$ ); (b) Hall and Johnston, ibid., 88, 1920 (1936) (6.6 $\gamma$ ); (c) Smith and Matheson, Bur. Standards J. Research, 17, 625 (1936) ( $8.6 \gamma$ ).
(3) (a) Hall and Jones, This Journal, 58, 1915 (1936) and the present paper; (b) Dole ${ }^{1}$ and This Journal, 58, 580 (1936); (c) Morita and Titani, Bull. Chem. Soc. Japan, 11, 419 (1936).
outlined by Urey and Greiff, ${ }^{4}$ that at high temperatures the constant of this reaction closely approaches unity (at $1000^{\circ} \mathrm{A}$., K is 1.0038 , at $1500^{\circ} \mathrm{A} ., \mathrm{K}$ is 1.0002 , at $2500^{\circ} \mathrm{A}, \mathrm{K}$ is 1.0004 ), and that the departure of oxygen from a perfectly random atomic distribution in the three molecular forms is negligible in this temperature range.

Consequently, at $1500^{\circ} \mathrm{A}$, for example, the $\mathrm{O}^{18} / \mathrm{O}^{16}$ ratio of a sample of water in equilibrium with a large excess of air should be the same as in the air within $0.1 \gamma$ (water density at $25^{\circ}$ ) and within $0.09 \gamma$ at $2000^{\circ} \mathrm{A}$. These differences are less than the probable error of the density determination. If then a sample of ordinary water were vaporized, heated with excess air and recondensed, its density should measurably increase, provided (a) air oxygen is really heavier and (b) there is an approach to equilibrium. The $D / H$ ratio should remain unaffected.

Assuming that $7 \gamma$ is the correct value of the Dole effect for surface water, the equilibrium density increases to be expected are roughly

Table I

| $T,{ }^{\circ} \mathrm{A}$. | $\gamma$ | Ref. |
