The heat of the reaction is thus 10.1 kcal. The 4 kcal. greater heat of reaction than that which accompanies the hydration of crotonaldehyde is ex-

plained by a lower loss of resonance energy in the hydration of crotonic acid.

# The Reaction of Wijs Solution with Tung Oil

By S. W. WAN AND D. B. HU

Tung oil contains mainly the glycerides of eleostearic acid and oleic acid and its drying power is due to the former unsaturated acid. In estimating the degree of unsaturation of tung oil with Wijs solution, the presence of eleostearic glyceride causes much uncertainty because the iodine value thus obtained varies with experimental conditions such as temperature, concentration and relative amount of reagent, and time of contact between reagent and oil.<sup>1</sup> Various methods have been tried for determining the percentage of eleostearic acid glyceride in tung oil, but have given no concordant results. Among the most recent methods may be mentioned the combined bromine vapor and Wijs method,<sup>2</sup> the differential halogen absorption method,<sup>3</sup> the polymerization method,<sup>4</sup> and the diene number method.<sup>5</sup> The peculiar properties of eleostearic acid giving rise to analytical difficulties have been explained by Böeseken and co-workers by assigning to it the molecular constitution CH3(CH2)3CH=CHCH=CHCH=CH-(CH<sub>2</sub>)7COOH,<sup>6</sup> which, in the light of Thiele's theory of partial valency, is expected to absorb halogens in two stages represented as

(II)

With Wijs solution,  $X_2$  being a molecule of iodine monochloride, the first stage reaction is much faster and produces a chloro compound.<sup>6</sup> On the other hand, compounds with non-conjugate double bonds take up the theoretical amount of iodine chloride in a short time, forming iodochloro compounds.

ken, Hoogl, Broek and Smit, ibid., 46, 619 (1927).

This paper gives an account of the authors' attempt to apply the above-mentioned property of eleostearic acid to the determination of the concentration of its glyceride in tung oil, and an account of their investigation in the chemical kinetics of reaction (II).

Materials.—Glacial acetic acid, C. P., tested free from reducible substances. Iodine, C. P., twice resublimed. Sodium oxalate, C. P., giving an assay of 99.98%. Sodium thiosulfate, potassium iodide, carbon tetrachloride, oleic acid, potassium permanganate, all C. P. grade. Tung oil, supplied from the Chinese Vegetable Oil Corporation, Hankow.  $\alpha$ -Eleostearic acid, prepared according to the method of Thomas and Thomson,<sup>7</sup> m. p. 48.3°. Wijs solution, prepared according to the procedure given by Griffin<sup>8</sup> with the important modification that the iodine and chlorine contents in the solution were adjusted to be exactly equivalent in amount.

The sodium thiosulfate solutions used in these experiments were standardized against potassium permanganate as a secondary standard and sodium oxalate as a primary standard.

### Experimental

Part I.--Approximately equal weights of the carbon tetrachloride solution of a sample were placed in glassstoppered conical flasks. To each was then added a weighed amount of Wijs solution and the mixture allowed to react for a definite length of time by shaking in a thermostat maintained at  $25 \pm 0.1^{\circ}$ . All reagents also had been allowed previously to reach temperature equilibrium in the same thermostat. The reaction in each mixture was stopped promptly by adding 20 cc. of 15% potassium iodide solution and the reaction mixture was immediately diluted with water and titrated with sodium thiosulfate solution from a weighing buret. A number of runs were made by following the above procedure and using samples of: (a) pure  $\alpha$ -eleostearic acid with a reaction period of five minutes; (b) pure  $\alpha$ -eleostearic acid with a reaction period of two minutes; (c) pure  $\alpha$ -eleostearic acid with a reaction period of ten minutes; (d) pure oleic acid with a reaction period of ten minutes; (e) a known mixture of  $\alpha$ -eleostearic and oleic acids with a reaction period of five minutes; (f) tung oil with a reaction period of five minutes.

Part II.— $\alpha$ -Eleostearic acid was weighed into a 100-cc. volumetric flask and carbon tetrachloride was added, mak-

ing up to volume at 25.0°. This solution was transferred into a glass-stoppered conical flask containing the Wijs solution previously set in the same thermostat maintained at  $25.0 \pm 0.1^{\circ}$ . While beginning the delivery of the carbon tetrachloride solution of  $\alpha$ -eleostearic acid two stopwatches were started simultaneously, one of them being stopped just when the delivery was completed, and the time of half delivery was taken as the starting point of the reaction. The flask containing the reaction mixture was well shaken at the start and also occasionally as the reaction went on. At definite intervals, 25-cc. portions of the reaction mixture were withdrawn with a pipet and each portion was delivered into one of a series of 120-cc. cork-stoppered conical flasks containing about 20 cc. of 15% potassium iodide solution. The duration for this delivery was noted and its half value was considered as the stopping point of the reaction. Each flask had been weighed with the potassium iodide solution in it and was again weighed after adding the reaction mixture. The exact volume of a portion of the mixture thus withdrawn was calculated from its weight and the density of the reaction mixture. (The densities of the eleostearic acid solution and that of Wijs solution were found to be additive.) The contents of the flask were transferred quickly and washed into a 300-cc. flask and titrated with sodium thiosulfate solution from a weighing buret. By following the above procedure the following investigations were performed: (g) reaction between  $\alpha$ -eleostearic acid and Wijs solution in conventional proportions; (h) reaction between  $\alpha$ -eleostearic acid and an equivalent amount of Wijs solution just sufficient for the first stage saturation; (i) reaction between  $\alpha$ -eleostearic acid and an excess of Wijs solution; (j) comparison of halogen absorption by  $\alpha$ -eleostearic acid and by tung oil.

#### Results

For experiments in part (I), solutions of  $\alpha$ eleostearic acid were of the concentration of about 0.015 millimole per gram of solution; solutions of oleic acid were of the concentration of about 0.022 millimole per gram of solution; the concentration of Wijs solution was 0.1450 millimole of iodine monochloride per gram of solution and 1 g. of the sodium thiosulfate solution was equivalent to 0.06295 millimole of halogen. All original data have been converted into millimoles of iodine monochloride used per millimole or gram of sample, and millimoles of halogen absorbed or left over per millimole or gram of sample, respectively; these results are given in Table I.

Results of Part II are given in Tables II to VI, where a is the molar concentration of  $\alpha$ -eleostearic acid in the mixture or in other words the initial concentration of  $\alpha$ -eleostearic acid tetrachloride at the beginning of the second stage reaction; b is the initial molar concentration of iodine monochloride at the beginning of the second stage; b' which is equal to 2a is the initial molar

concentration of free iodine liberated during the first stage; B is the sum of b and b'; x' is the molar concentration of the iodochloride of  $\alpha$ -eleostearic acid tetrachloride and x'', that of the di-iodide of  $\alpha$ -eleostearic acid tetrachloride formed during time t of the reaction; x is the sum of x' and x'';  $k_1$ ,  $k_1^*$ ,  $k_2$ ,  $k_2^*$ , and  $k_3$  are specific reaction rates described in another section of this paper (see Discussion).

## Discussion

The interpretation of the results from the experiments of part (I) is based on the following consideration. When x, representing the number of millimoles of iodine monochloride added to one millimole of acid, is plotted against y, the number of millimoles of halogen absorbed, then in the case of  $\alpha$ -eleostearic acid, a linear relation, y = x/2, will be obtained until the point, y = 2, x = 4, is reached, because this acid absorbs chlorine and not iodine in the first stage reaction, each millimole of acid requiring two of chlorine obtainable from four of iodine monochloride. Beyond this point the plot will become a horizontal straight line, y = 2.

However, the above relation is valid only when the reaction period is long enough for completing the first stage absorption but not too long lest the second stage reaction become appreciable.  $\mathbf{If}$ the second stage reaction takes place to an appreciable extent along with the first stage reaction, the plot will not be linear; if the reaction period is too short for the first stage saturation, the first part of the plot will have a slope less than 1/2; and if the reaction period is too long for the first stage saturation, the first part of the plot will have a slope greater than 1/2. Furthermore, if the second stage reaction can be detected in the presence of excess iodine monochloride, the second part of the plot will not be horizontal and not necessarily linear. These phenomena are clearly illustrated by Figs. 1, 2 and 3, in which are plotted the results of experiments (a), (b) and (c).

The results obtained from the reaction of oleic acid and iodine monochloride when treated in the same manner give a decisive answer to the question whether oleic acid absorbs chlorine alone or a whole molecule of iodine monochloride. Since oleic acid contains one double bond, the plot, in the former case, will be  $y = \frac{1}{2}x$  up to x = 2,

y = 1, and become y = 1 beyond that, while in the latter case it will be simply y = x up to x = 1, y = 1 and then become y = 1 beyond that. On the other hand, if u represents the millimoles of iodine monochloride added to one of acid, and v, the millimoles of halogen left over, the plot will be u = 2v up to u = 2 and v = 1, and become u = vfurther on, in the former case; in the latter case, u = v + 1 throughout. The intercept of 1 on the u-axis is clearly brought out in Fig. 4.

With a mixture of the two acids, the results have been plotted on the basis of x millimoles of iodine monochloride added per gram of sample against y millimoles of halogen absorbed. Let r and s be the weight fractions;  $m_e$  and  $m_o$ , the millimolecular weights of  $\alpha$ -eleostearic acid and oleic acid, respectively; p, the point at which just enough iodine monochloride has been used to satisfy both the oleic acid and the eleostearic acid first stage saturation. From the knowledge gained in these experiments concerning the behavior of iodine monochloride toward the two acids, it is evident that

$$x_{\rm p} = 4 \frac{r}{m_{\rm e}} + \frac{s}{m_{\rm e}}$$
 and  $y_{\rm p} = 2 \frac{r}{m_{\rm e}} + \frac{s}{m_{\rm e}}$ 

Hence r and s can be solved for simultaneously from the above equations.

In our analysis of a known mixture by this method, there has been good agreement between the actual and the calculated values for  $\alpha$ -eleostearic acid (see Fig. 5). Only one determination

has been made with tung oil (see Fig. 6) but further investigation is in progress because on the whole the method thus developed seems very promising.

The data of experimental part (II) are the first of the kind making possible a study of the chemical kinetics for the reaction between  $\alpha$ eleostearic acid and iodine monochloride. For this reaction Böeseken<sup>6</sup> has proposed the scheme CH<sub>3</sub>(CH<sub>2</sub>)<sub>5</sub>CH=CHCH=CHCH=CH(CH<sub>2</sub>)<sub>7</sub>COOH + 4 ICl  $\longrightarrow$  CH<sub>4</sub>(CH<sub>2</sub>)<sub>5</sub>CHCICHCICHCICHCI-(CH<sub>2</sub>)<sub>7</sub>COOH + 2I<sub>2</sub>  $\xrightarrow{+ ICl}$  CH (CH<sub>2</sub>)<sub>5</sub>CHCICHCICHCI-CHCICHCICHCI(CH<sub>2</sub>)<sub>7</sub>COOH (III)

The second stage reaction according to the above scheme is bimolecular and therefore its reaction rate  $k_1$  can be expressed by the second order relation

$$k_1 = 1/t(a - b) \ln b(a - x)/a(b - x)$$
 (IV)

However, if the absorption involves the addition of chlorine or iodine (from iodine monochloride), instead of iodine monochloride itself, the specific reaction rate  $k_1^x$  of a third order reaction would be obtained from the equations

$$dx/dt = k_1^*(a - x)(b - 2x)^2$$
 (V)

and  $\mathbf{a}$ 

$$k_1^* = 1/t(b - 2a)\{1/(b - 2a) \ln a(b - 2x)/b(a - x) - 1/(b - 2x) + 1/b\}$$
(VI)

There is still another possibility, namely, the absorption of iodine (liberated in the first stage) and iodine monochloride simultaneously in the second stage. In this case, the reaction rate would be governed by the relation

$$dx/dt = k_2(a - x)(b - x') - k_3(a - x)(b' - x'') \quad (VII)$$

The integration of equation (VII) would be a laborious process but as a first approximation the calculation may be simplified by either one of the following conditions. (1) The iodine monochloride concentration is just sufficient to complete the first stage absorption, so that b = 0 and x' = 0and equation (VII) reduces to

$$dx/dt = k_3(a - x)(b' - x'') = k_3(a - x)(b' - x)$$
(VIII)

and

$$k_{\rm s} = 1/t(b'-a) \ln a(b'-x)/b'(a-x) \quad ({\rm IX})$$

(2) When excess of iodine monochloride is used, the relatively small amount of iodine liberated in the first stage may be disregarded so that equation (VII) becomes

 $\mathrm{d}x/\mathrm{d}t = k_2(a - x)(b - x')$ 

 $= k_2(a - x)(b - x)$ 

and

$$k_2 = 1/t(b - a) \ln a(b - x)/b(a - x)$$
 (XI)

The fact that values of  $k_1$  and  $k_1^*$  given in Table II fail to correlate with equations (IV) and (VI), respectively, indicates that the mechanism suggested by Böeseken for the second stage reaction between iodine monochloride and  $\alpha$ eleostearic acid is incorrect, and that it is neither bimolecular nor trimolecular but most probably a combination of two simultaneous bimolecular reactions, one between the acid and the iodine liberated in the first stage and the other between the acid and iodine monochloride. This statement is supported by the data given in Table III and Table IV and plotted in Fig. 7 and Fig. 8 to show the linear relation between t and  $\ln (b' - x)/(b' - x)$ (a - x) and between t and  $\ln (b - x)/(a - x)$ , respectively. It should be noted that when the

(X)

above plots are extrapolated to zero time, the values of  $\ln (b/a)$  and  $\ln (b'/a)$  are higher than the corresponding computed values. This may be accounted for by the presence of the beta form of eleostearic acid produced from the alpha acid on standing, the beta acid having a lower halogen-absorption rate.<sup>10</sup> Furthermore, the prompt stopping of a reaction in these experiments was done through adding to the reaction mixture, an excess of potassium iodide solution which might react with the iodo-chloride of  $\alpha$ -eleostearic acid addition product forming a di-iodide which in turn might liberate iodine and restore the last-saturated double bond.<sup>6</sup>

The specific reaction rates  $k_2$  and  $k_3$  of the abovementioned simultaneous bimolecular reactions are both small and of the same order of magnitude. If they could be assumed equal, equation (VII) would become

$$dx/dt = k_4(a - x)(b + b') - (x' + x'') = k_4(a - x)(B - x)$$
(XII)

which is equivalent to a second order equation. As a matter of fact, a linear relation is obtained between t and log (B - x)/(a - x) as shown in Fig. 9, which apparently confirms the contention made previously on the absorption of halogen by  $\alpha$ -eleostearic acid in Wijs solution that the mechanism of the reaction is bimolecular.

The similarity of the two curves in Fig. 10 serves to indicate that the reaction of halogen in Wijs solution with tung oil is much of the same nature as that with  $\alpha$ -eleostearic acid. This property also has been applied in experimental part (I).

The increase of iodine value of the oil with increase of temperature or time of contact with Wijs solution can be explained easily in the light of what has been found from these experiments. The absorption of chlorine from iodine monochloride in the first stage explains the requirement of a minimum excess of Wijs solution for obtaining a normal iodine value.<sup>1</sup> The slight decrease of iodine value with increased amount of oil when the

(10) Van Loon, Chem. Umschau, Feite, Oele, Wachse, Harze, 37, 269 (1930).

same amount of Wijs solution is used<sup>11</sup> may be accounted for by the fact that a relatively larger amount of  $\alpha$ -eleostearic acid glyceride absorbs a correspondingly larger amount of iodine monochloride in the first stage and leaves a smaller excess of halogen which because of the kinetic relations mentioned above decreases the rate of halogen absorption in the second stage.

Finally, attention should be called to the fact that although experiment (i) was aimed at using a large excess of iodine monochloride relative to  $\alpha$ -eleostearic acid so that b' and x'' might become insignificant compared with b and x', yet practical limitations made it possible to realize only a ratio of about 10 to 1 between b and b'. This ratio may not justify the process of simplifying equation (VII) to equation (X). Most probably errors have been introduced into the values of  $k_2$  by this simplifying process which makes it necessary to use an extrapolated value for log (b/a) in order to obtain a fairly constant  $k_2^*$ . A more direct and accurate determination of both  $k_2$  and  $k_3$  is highly desirable. The authors are making this investigation.

# Summary

1. The behavior of Wijs solution toward  $\alpha$ eleostearic acid, oleic acid and a mixture of the two acids has been studied by varying the proportion of Wijs solution to acid and the time of contact.

2. The two-stage halogen absorption from Wijs solution by  $\alpha$ -eleostearic acid forming a tetrachloro addition product in the first stage, and the addition of iodine monochloride to oleic acid have been quantitatively established.

3. The difference in halogen absorption between  $\alpha$ -eleostearic acid and oleic acid has been applied to the analysis of a mixture of the two acids and to the analysis of  $\alpha$ -eleostearic acid (11) Chemistry (China). 1, 1 (1934). Sept., 1939

glyceride in tung oil, further work being carried on for developing the latter analysis into a reliable method.

4. The chemical kinetics for the absorption of halogen from Wijs solution by  $\alpha$ -eleostearic acid has been studied and two specific

reaction rates have been determined.

5. Böeseken's assumption of a bimolecular reaction for the second stage halogen absorption by  $\alpha$ -eleostearic acid from Wijs solution has been

found incorrect. A combination of two simultaneous bimolecular reactions has been suggested

CH<sub>3</sub>(CH<sub>2</sub>)<sub>3</sub>CHClCHClCH=CHCHClCHCl(CH<sub>2</sub>)<sub>7</sub>COOH

 $\xrightarrow{+\mathrm{ICl}} \mathrm{CH}_{3}(\mathrm{CH}_{2})_{3}\mathrm{CHCiCHCiCHICHCiCHCiCHCi(CH_{2})_{7}COOH}$   $\xrightarrow{+\mathrm{I}_{2}} \mathrm{CH}_{3}(\mathrm{CH}_{2})_{3}\mathrm{CHCiCHCiCHICHICHCiCHCi(CH_{2})_{7}COOH}$ 

6. The variation of the iodine value of tung oil with temperature, excess of reagent and time of contact with reagent has been explained.

# Physicochemical Studies of Alpha and Beta Eleostearic Acids. I. Molar Refractivity and Parachor

## By S. W. WAN AND M. C. CHEN

Alpha and beta eleostearic acids were names suggested by Maquenne<sup>1</sup> for the isomeric eleomargaric and eleostearic acids so named and first isolated from the oil of Eleococca Vernicia by Cloez.<sup>2</sup> Tung oil is mainly a triglyceride of the alpha acid, and because of its special properties which make tung oil a highly important and useful material, a large amount of data has been accumulated. However, there were differences in opinion concerning its constitution<sup>3</sup> until Böeseken and co-workers<sup>4</sup> suggested the formula, CH<sub>3</sub>(CH<sub>2</sub>)<sub>3</sub>CH=CHCH=CHCH=CH(CH<sub>2</sub>)<sub>7</sub>CO-OH which has correlated many important phenomena not satisfactorily explained before. Although experimental findings from different sources have not entirely converged toward a common conclusion, most investigations seem to confirm this constitution.

One of the arguments put forth by Böeseken and co-workers<sup>4</sup> for suggesting the above formula was based upon the molar refractivity of the eleostearic acids. Melting points of 47 and  $67^{\circ}$  were given, respectively, for the specimens of alpha and beta isomers prepared for their experiments. Since then the method of preparation has been

The authors have followed the method of Thomas and Thomson<sup>5</sup> with increased repetition of recrystallization, and have obtained from a large batch of original crystals a small crop of highly purified product with melting points higher than the previously reported values. A series of physicochemical determinations is being made with the highly purified alpha and beta eleostearic acids thus obtained.

**Experiments and Data.**—Alpha and beta eleostearic acids were prepared from their corresponding glycerides in tung oil, the beta-glyceride being formed when tung oil was allowed to stand in contact with a trace of sulfur. Density, surface tension and index of refraction of the alpha and beta acids were determined, respectively, at  $50 \pm 0.01^{\circ}$  and  $75 \pm 0.01^{\circ}$ . The surface tension of each was measured by the capillary rise method and the index of refraction by the use of an Abbe refractometer. The following data were obtained.

TABLE I					
Acid	$\alpha$ -Eleostearic	$\beta$ -Eleostearic			
Melting point, °C.	49.0-49.2	71.5 - 72.0			
Density	0.9028 at 50°	$0.8909~{ m at}~75^\circ$			
Surface tension	33.42 at 50°	<b>3</b> 1.04 at 75°			
Refractive index	1. <b>5112 at 5</b> 0°	1.5022 at 75°			

# **Results and Discussion**

From the above data the parachor, P, and molar refractivity, R, of the eleostearic acids were calculated and are given in Tables II and III. P'and R' in the tables are, respectively, the theoreti-
