

It should be mentioned, also, that Horner, Hoffmann, Wippel and Hassel³ have determined the major product in each of the reactions of a series of *p*-Y-phenyltriphenylphosphonium halides with sodium hydroxide, and they found that the relative ease of elimination of groups parallels the anionic stability.

BOOK REVIEWS

Chemie der Azofarbstoffe. By HEINRICH ZOLLINGER, Privatdozent an der Universität Basel. Birkhäuser Verlag, Elizabethenstrasse 19, Basel 10, Switzerland. 1958. 308 pp. 17.5 × 24.5 cm. Price, sFr. 36.25.

This approach to the chemistry of azo dyes has been made from the physical-organic chemist's point of view, which has been subordinate in the various books published about dye chemistry since the last war.

The material employed in the book is completely up-to-date and thoroughly documented. In keeping with the purely scientific nature of the text, reference to patents is very meager. In at least one instance, reliance on patent information has been independently verified (see ref. 44 on p. 79). Twenty-eight references chosen at random were found to be entirely accurate.

The material is easily read and the presentation is straightforward. No mechanism or theory is put forward or developed without adequate definition of the terms used. The organization of the topics discussed is logical and orderly. The first chapter is devoted to the concepts, definitions and methods of studying reaction mechanisms. The next six are concerned with diazo and diazonium compounds. Methods and mechanisms of diazotization, equilibria and isomerisms, and decomposition reactions of diazo and diazoamino compounds are thoroughly discussed. Chapters 8 and 9 present methods of preparing azo compounds and the mechanisms of the most important method, the coupling reaction. Chapter 10 should prove fruitful to the organic dye chemist since it explains the application of coupling theories to the technology of azo dyes. The next chapter (11) is the only one in which the subject matter is treated from a strictly organic point of view. It explains the nomenclature and classification of azo dyes from the technical aspect, and contains seven sections in which the chemistry of the most important classes is concisely but clearly explained and illustrated. There is also an interesting table of the most important developments in the azo dye industry, presented in chronological order. Chapter 12 deals with the relation between constitution and properties of azo dyes. There is an excellent general summary on structure and light absorption of organic compounds, and a discourse on the relation of color as seen by the eye to the spectral absorption curve. The tautomerism and acid-base equilibria of azo dyes are also discussed. It is a disappointment to this reviewer that a section on correlation of structure to light fading of azo dyes, which would seem to belong to this chapter, was not included. It is true that this particular aspect of dye chemistry is quite confused, but emphasis of this fact might have given impetus to a truly scientific study of light fastness. A valuable aid to the industrial dyer would have been the inclusion of a section concerned with structure and ease of reduction, which is important in such applications as discharge printing. Chapter 13, which presents the chemistry of metallic complexes, is indeed timely because of the growing importance of the relatively new, so-called "neutral dyeing" complexes for nitrogenous fibers. The nature of the complex bonds, and the equilibrium, stability and stereochemistry of the complexes are nicely portrayed. No doubt, the last two chapters in the book will be considered by some as not properly belonging here because their scope is greater than the use of only azo dyes. These are concerned with

the use of dyes on various fibers and the physical chemistry of the dyeing processes. However, certainly no harm is done and, if the book is to be used as a text, the condensed treatment employed will, for many purposes, eliminate references to more lengthy and cumbersome treatises.

A few minor criticisms, which do not detract seriously from the general usefulness of the book, are to be noted. The indexing appears to be incomplete; for example, structural formulas for triphenodioxazines appear twice in the text, but no reference to them is found in the index. Also, reference to reports based on captured German documents is rather loose; for example, reference 20 on page 115 is given simply as "FIAT-Report 1313." Since this latter is a three-volume work of about 1400 pages, the reader might find it annoying to ferret out the desired information without more specific instruction.

The printing, paper, and binding of the book are of high quality.

Dr. Zollinger's book is a must for the azo dye research chemist and is suitable as a text, especially at the graduate level. It is hoped that this treatise, together with the recent books of a more organic and technological nature, will stimulate American colleges to offer courses in dye chemistry.

J. M. STRALEY

Outlines of Enzyme Chemistry. Second Edition, Revised and Enlarged. By J. B. NEILANDS, Department of Biochemistry, University of California, and PAUL K. STUMPF, Department of Agricultural Biochemistry, University of California. John Wiley and Sons, Inc., 440 Fourth Avenue, New York 16, N. Y. 1958. xii + 411 pp. 15.5 × 23.5 cm. Price, \$8.50.

In view of the rapid accumulation of new information and continual modification of research trends in the field of enzymology, the prompt appearance of a new edition of even an elementary textbook of enzymology such as "Outlines of Enzyme Chemistry" is very welcome. The second edition retains the character and general organization of the first, but has been expanded approximately 30 per cent. Most chapters show judicious revision with only minor expansion, but greatly enlarged discussions or new chapters are offered in several areas of current research interest or rapid recent development.

The book, with 27 chapters, is organized into four sections, of which the first two are concerned with general principles and the physical chemistry of enzymes. The first section includes brief but valuable chapters of general and historical introduction, enzyme isolation methods, criteria of purity and characterization of enzymes. The physical chemical aspects of enzymology are given extended, lucid treatment at a fairly elementary level, with separate chapters devoted to chemical and hydrogen ion equilibria, metal-ion equilibria, kinetics, effects of substrate concentration, of pH, and of temperature, action of inhibitors, energetics-oxidation-reduction, specificity of enzymes, and mech,
