function for (11b). By substituting (13) in (11b) and taking the sum of the values for all the electrons, one obtains $\sigma_{z}$ of the molecule

$$
\begin{align*}
& \sigma_{\mathrm{z}}=\left(e^{2} / 2 m c^{2}\right) \sum_{i}\left[\left(\left(x_{\mathrm{i}}^{2}+y_{\mathrm{i}}^{2}\right) / r_{\mathrm{i}}^{3}\right)-\right. \\
&\left.\left(x_{\mathrm{i}}\right)\left(x_{\mathrm{i}} / r_{\mathrm{i}}{ }^{3}\right)-\left(y_{\mathrm{i}}\right)\left(y_{\mathrm{i}} / r_{\mathrm{i}}^{3}\right)\right] \tag{14b}
\end{align*}
$$

Averaging the molecular values for all orientation of a molecule gives

$$
\begin{align*}
\sigma_{\mathrm{av}} & =\left(\sigma_{\mathrm{x}}+\sigma_{\mathrm{y}}+\sigma_{z}\right) / 3 \\
& =\left(e^{2} / 3 m c^{2}\right) \sum_{i}\left[\left(1 / r_{\mathrm{i}}\right)-\left(x_{\mathrm{i}}\right)\left(x_{1} / r_{\mathrm{i}}^{3}\right)-\right. \\
& \left.\quad\left(y_{\mathrm{i}}\right\rangle\left(y_{\mathrm{i}} / r_{1}^{3}\right)-\left(z_{\mathrm{i}}\right\rangle\left(z_{\mathrm{i}} / r_{1}^{3}\right)\right] \tag{15b}
\end{align*}
$$

Equations 14 b and $1 \overline{\mathrm{~b}} \mathrm{~b}$ are identical with those proposed by Ito. ${ }^{3}$ If one assumes that $h=x y$, eq. 11 b gives the formula proposed by Das and Bersohn. ${ }^{7}$

The comments on the form of $h$ which were given under the discussion of diamagnetic susceptibility hold also for the nuclear magnetic shielding constant. ${ }^{16}$ Therefore eq. 14 b and 15 b should give satisfactory results for (a) the types of molecules to which (14a) and (15a) are applicable, and (b) for the effects of electrons localized at atoms relatively distant from the nucleus under study; (14b) and (15b) have been applied in a few cases. ${ }^{3}$

## III. Electronic Polarizability

The effective Hamiltonian of an electron under an external electric field $E$ may be expressed in the form of (1) with

$$
\begin{align*}
\chi^{(1)} & =e z E \\
\chi^{(2)} & =0
\end{align*}
$$

where the field is along the $z$-axis. By the use of the variational function (4), the energy $W$ of the perturbed electron may be expressed in the form of (7) with
(16) H. F. Hameka, Mol. Phys., 1, 203 (1958).

$$
\begin{align*}
A & =W_{0}+e E(z) \\
B & =2 e E((z g)-(z)(g)) \\
C & =\left(h^{2} / 2 m\right)\left((\nabla g)^{2}+(\nabla h)^{2}\right)
\end{align*}
$$

The electronic polarizability $\alpha$ is defined by the coefficient in a power series

$$
\tilde{W}=W_{0}-\left(\alpha_{z} / 2\right) E^{2}+\cdots
$$

Then substitution of ( $9^{\prime}$ ) in (7) gives

$$
\alpha_{z}=\left(4 / a_{0}\right)((z g)-(z)(g))^{2} /\left((\nabla g)^{2}+(\nabla h)^{2}\right) \quad(11 \mathrm{c})
$$

where $a_{0}$ is the Bohr radius. For minimunn $W$ ( $10^{\prime}$ ), function $h$ is made equal to zero. Function $g$ is assumed to have a form analogous to (12)

$$
\begin{equation*}
g=a x+b y+c z \tag{12}
\end{equation*}
$$

Substitution of (12') in (11c) and determination of the ratio $a: b: c$ for the minimum energy ( $10^{\prime}$ ) gives
$a: b: c=((x z)-(x)(z)):((y z)-$

$$
(y)(s)):\left(\left(s^{2}\right)-(z)^{2}\right) \quad\left(13^{\prime}\right)
$$

By substituting (12') and (13') in (11c) and taking the sum of the values for all the electrons, one obtains the molecular electronic polarizability

$$
\begin{aligned}
\alpha_{z}=\left(4 / a_{0}\right) \sum_{i} & {\left[\left(\left(x_{i} z_{i}\right)-\left(x_{i}\right)\left(z_{i}\right)\right)^{2}+\right.} \\
& \left.\left(\left(y_{i} z\right)-\left(y_{\mathrm{i}}\right)\left(z_{i}\right)\right)^{2}+\left(\left(z_{\mathrm{i}}^{2}\right)-\left(z_{i}\right)^{2}\right)^{2}\right] \quad(14 \mathrm{c})
\end{aligned}
$$

The mean value of $\alpha$ is given by

$$
\begin{align*}
\alpha_{\mathrm{av}}= & \left(\alpha_{\mathrm{x}}+\alpha_{y}+\alpha_{z}\right) / 3 \\
= & \left(4 / 3 a_{0}\right) \sum_{i}\left[\left(\left(x_{\mathrm{i}}^{2}\right)-\left(x_{\mathrm{i}}\right)^{2}\right)^{2}+\left(\left(y_{i}^{2}\right)-\right.\right. \\
& \left.\left\langle y_{i}\right)^{2}\right)^{2}+\left(\left(z_{i}^{2}\right\rangle-\left(z_{i}\right)^{2}\right)^{2}+2\left(\left(x_{i} y_{\mathrm{i}}\right)-\right. \\
& \left.\left(x_{\mathrm{i}}\right)\left(y_{i}\right)\right)^{2}+2\left(\left\langle y_{i} z_{\mathrm{i}}\right)-\left(y_{\mathrm{i}}\right)\left(z_{i}\right\rangle\right)^{2}+ \\
& \left.2\left(\left(z_{i} x_{\mathrm{i}}\right)-\left\langle z_{\mathrm{i}}\right)\left(x_{\mathrm{i}}\right)\right)^{2}\right] \tag{15c}
\end{align*}
$$

Equations 14 c and $1 \overline{\mathrm{c}} \mathrm{c}$ are independent of the choice of the origin. For atoms, eq. 15 c gives the well known formula

$$
\alpha_{\mathrm{av}}=\left(4 / 9 a_{0}\right) \sum_{i}\left(r_{\mathrm{i}}^{2}\right)^{2}
$$

Nagoya, Japan

## [Contribution from the Department of Chemistry, Cornell University]

## Dipole Moments and Optical Dispersion of Perchloro-fluorobutanes, Butadienes, Butenes and Propylenes ${ }^{1}$

By Emile Rutner and S. H. Bauer<br>Received May 4, 1959

Dipole moments and refractive indices between 4358 and $6565 \AA$. were measured for a series of perchloro-fluorobutanes, butadienes, butenes and propylenes. The optical dispersion was found to obey the relation $\left(n_{\lambda}^{2}+2\right) /\left(n_{\lambda}^{2}-1\right)=a+c_{i}$. $\left[1 / \lambda^{2}-1 / \lambda_{\mathrm{i}}^{2}\right]$, where $\lambda_{\mathrm{i}}$ is a "characteristic frequency," and $a$ and $c_{\mathrm{i}}$ are constants characteristic of the substance. From the increments in refractivities for the substitution of F for Cl for a series of fluorocarbons, a consistent set of bond refractivities was deduced for the CF bond ( 1.75 cc .) and for the CCl bond ( 6.48 cc .) in a perhalogenated environment. Similarly, by using the increment of dipole moment for the substitution of F for $\mathrm{Cl}(0.5 \mathrm{D})$ in a perhalogenated environment and a value of $\mu$ ( $1.05 D$ ) for the CCl bond moment, the minimum, maximum and free rotation dipole moments for the series of perhalocarbons studied were calculated and related to the measured dipole moments. The barrier height hindering free rotation in $\mathrm{CF}_{2}=\mathrm{CCl}-\mathrm{CCl}=\mathrm{CF}_{2}$ was estimated from the measured dipole moment ( 0.35 D ).

Data on the optical dispersions and dipole moments of perhalogenated butanes, butenes and butadienes have not as yet been reported. A study of these molecular properties of perchloro-fluorobutanes, butenes, butadienes and propylenes was
(1) Part of the Ph.D. Thesis, submitted by E. Rutner, to the Faculty of the Graduate School, Cornell University, June, 1951.
undertaken with the expectation of relating the evident trends in these properties to the corresponding changes in molecular structures.

## Experimental

Materials.-The synthesis and purification of some of the compounds used will be described elsewhere ${ }^{2}$; herein we have
(2) W. T. Miller and E. Rutner (to be published).

$4358 \AA$.
${ }^{a}$ Measurements made at $20.00 \pm 0.05^{\circ}$. Mixtures of isomers.
listed the estimated purities based on distillation and/or freezing point curves, given in parentheses after each compound. These other compounds will be described in the forthcoming publication ${ }^{2}$ : $\mathrm{CCl}_{2} \mathrm{FCCl}_{2} \mathrm{CCl}_{2} \mathrm{CCl}_{2} \mathrm{~F}$ ( $>99.9$ ), $\mathrm{CCl}_{2} \mathrm{FCCl}_{2} \mathrm{CCl}_{2} \mathrm{CClF}_{2}$ ( $>99.9$ ), $\quad \mathrm{CClF}_{2} \mathrm{CCl}_{2} \mathrm{CCl}_{2} \mathrm{CClF}_{2}$ ( $>99.0$ ), $\mathrm{CClF}=\mathrm{CClCCl}=\mathrm{CClF}$ ( $>99.0$ ), $\mathrm{CClF}=\mathrm{CClCl}$ $=\mathrm{CF}_{2}(>99.0), \mathrm{CF}_{2}=\mathrm{CClCCl}^{2}=\mathrm{CF}_{2}(>99.9)$. Additional compounds were supplied by the persons noted: A. H. Fainberg, $\mathrm{CCl}_{2}=\mathrm{CClCCl}_{3}$ ( $>99.5$ ), $\mathrm{CCl}_{2}=\mathrm{CClCF}_{3}$ ( $>99.0$ ); R. T. Carroll, $\mathrm{CCl}_{2} \mathrm{FCClFCClFCCl} 2 \mathrm{~F}(>99.0), \mathrm{CClF}=$ $\mathrm{CClFCClF}=\mathrm{CClF}(>99.0) ; \mathrm{F}$. W. McLafferty, a mixture of $\mathrm{CCl}_{2}=\mathrm{CClCCl}_{2} \mathrm{CCl}_{3}$ and $\mathrm{CCl}_{3} \mathrm{CCl}=\mathrm{CClCCl}_{3}, n-\mathrm{C}_{4} \mathrm{Cl}_{10}(>$ 99.0 ); W. E. Tait, $\mathrm{CF}_{3} \mathrm{CCl}_{2} \mathrm{CCl}_{2} \mathrm{CF}_{3}(>99.0), \mathrm{CF}_{3} \mathrm{CCl}=$ $\mathrm{CClCF}_{3}$ (>99.0).
Two compounds were obtained from commercial sources. The fluorobenzene (Eastman Kodak Company, pure grade) was distilled through a $70 \times 1.6 \mathrm{~cm}$. packed column; the $50 \%$ center fraction had the physical properties listed: b.p. $84.6^{\circ}$ ( 740 mm .), f.p. $-41.7^{\circ}, n^{20} \mathrm{D} 1.4677$; Smakula ${ }^{3}$ gives b.p. $85.0^{\circ}$ ( 760 mm .), f.p. $-41.9^{\circ}, n^{20} \mathrm{D} 1.4677$. Perchlorobutadiene was obtained from the Hooker Electrochemical Company and purified in the following manner. A 500 -cc. sample was washed with four or five $50-\mathrm{cc}$. volumes of methyl alcohol or until the yellow color had been extracted. The sample was then stirred for 2 hr . with sulfuric acid, washed with distilled water until neutral and filtered through a $3^{\prime \prime}$ column of $\mathrm{P}_{2} \mathrm{O}_{5}$. Finally, it was distilled through a $50 \times 3.0 \mathrm{~cm}$. packed column at 100 mm . pressure. The fraction containing $10 \%$ of the material after $80 \%$ had been distilled gave a cooling curve indicating that it was $99.9 \%$ pure. The physical properties of this fraction were: b.p. $144.1^{\circ}(100 \mathrm{~mm}$.$) , f.p. -18.6^{\circ}, n^{20} \mathrm{D} 1.5557, d^{20}{ }_{4} 1.6794$; Kohlrausch and Wittek ${ }^{4}$ gave b.p. $210-212^{\circ}$ ( 760 mm .), f.p. $-15^{\circ}, n^{20} \mathrm{D} 1.5556$.

The solvents used were carefully purified; cyclohexane, according to the technique described by Bruun and HicksBruun, ${ }^{5}$ had these physical properties: f.p. $6.5 \pm$ $0.1^{\circ}, n^{20} \mathrm{D} 1.4262, d^{20} 0.7785 ;$ the literature ${ }^{6}$ gives f.p. $6.554^{\circ}, n^{20} \mathrm{D} 1.4263, d^{20{ }_{4}^{4}} 0.7785$. Benzene, Baker and Adamson reagent grade, was distilled in the presence of sodium. The fraction used had: $n^{20} \mathrm{D} 1.5010, d^{20}{ }_{4} 0.8787$; the literature ${ }^{6}$ gives $n^{20_{\mathrm{D}}} 1.5010, d^{20_{4}} 0.8789$.

Handling of Samples.-Since the perhalogenated butadienes are readily oxidized, precautions were taken to minimize exposure to the atmosphere. Into a number of prepared flasks, about 100 g . of the butadienes was distilled under a nitrogen blanket; the flasks were sealed. These were later attached to a manifold containing a plug of Ascarite and Dehydrite; attached also were several pear-shaped flasks with small glass bulbs which had been weighed. The manifold was evacuated; the sample was distilled back and forth over the Ascarite several times and finally condensed into the pear-shaped flasks; nitrogen was admitted to the manifold to force the butadiene into the small bulbs. The manifold then was dismounted, the bulbs sealed and weighed.

[^0]Refractive index measurements were made with a Pulfrich refractometer; the cell was sealed to the prism by means of fish glue which had been treated according to the formula given by Strong. ${ }^{7}$. The samples were either poured or distilled into the cell which was covered by a condenser.

The light sources used were: (a) a sodium lamp, (b) a hydrogen discharge tube and (c) a mercury lamp. The desired lines were selected by means of filters: $6565 \AA$. (b), $5893 \AA$. (a) , $5770 \AA$. (c), $5016 \AA$. (b), and $4358 \AA$. (c). The prisms were calibrated at each wave length using the data given by Lowry and Alsopp. ${ }^{8}$ All measurements shown in Table I were made at $20 \pm 0.05^{\circ}$ and are probably accurate to $\pm 0.00015$.
Dielectric constants were measured in the apparatus described by Keenan. ${ }^{9}$ In essence, it was a capacitance bridge operating as heterodyne beat oscillator, with a crystal control section oscillating at 1.57 megacycles; readings were taken on a vernier dial capacitor in parallel with the measuring cell. The apparatus was standardized with benzene and its accuracy checked with cyclohexane. The dielectric constant of benzene was taken as 2.283 at $20^{\circ}$ and of cyclohexane as $2.027^{10}$ at the same temperature. The accuracy of the dielectric constants was estimated to be $\pm 0.002$ on the basis of the data obtained for cyclohexane.
The cell used consisted of three concentric gold-plated brass cylinders similar to that described by Smyth. ${ }^{11}$ The first and third cylinders were grounded while the center one was suspended on Kel-F buttons, thus forming two condensers in parallel. The cell capacity filled with air was $38 \mu \mu \mathrm{f}$. and its volume 15 ml . The temperature of the cell was maintained at $20.0 \pm 0.15^{\circ}$ by means of an oil-bath.

## Treatment of the Data

Dispersion Data.-The data for each compound shown in Tables I and II were reduced using the relations ${ }^{10,12}$

$$
\begin{gather*}
\left(P_{\mathrm{E}}\right)_{\lambda}=\phi_{\lambda}(M / d)=\left[\left(n_{\lambda}^{2}-1\right) /\left(n_{\lambda}^{2}+2\right)\right](M / d)  \tag{1}\\
1 / \phi_{\lambda}=c_{\mathrm{i}}\left[\left(1 / \lambda^{2}\right)-\left(1 / \lambda_{\mathrm{i}}^{2}\right)\right]=a+\left(c_{\mathrm{i}} / \lambda^{2}\right) \tag{2}
\end{gather*}
$$

Subscript $\lambda$ designates the wave length at which the measurement was made; $P_{\mathrm{E}}$ is the electronic polarization; $n$, the refractive index; $M$, the molecular weight; and $d$, the density. A plot of $1 / \phi_{\lambda}$ was found to be linear with $1 / \lambda^{2}$ for most of the compounds, over the region 4358 to $6565 \AA$.;

${ }^{a}$ Constants for equation 2 ; i.e., $1 / \phi \lambda=a-c_{\mathrm{i}} / \lambda^{2} . \quad c_{\mathrm{i}}$ is then the slope of the plot and the intercept for $\lambda=\infty, 1 / \phi_{\infty}$ $=a$.
thus, $\lambda_{\mathrm{i}}$ was evaluated from the intercept extrapolated to $1 / \lambda^{2} \rightarrow 0$. The values of $P_{\mathrm{E}}^{\infty}$. and $P_{\mathrm{E}}^{\mathrm{D}}$, i.e., $\lambda \rightarrow \infty$, and $\lambda=\mathrm{Na}_{\mathrm{D}}$ were subsequently used in estimating the dipole moments. Values of $P_{E}$ for the solid compounds were obtained from polarization measurements of benzene solutions of the compounds, assuming that the molecular polarizations of the solvent and solute were additive. The refractive indices of benzene were taken from reference 8 . The significant deviations of the $P_{\mathrm{E}}^{\mathrm{D}}$ values deduced for the solid compounds from those calculated assuming bond additivity probably are due to the departure from strict additivity of the solute and solvent polarizabilities.

Polarization Data.-Dielectric constants of solutions of the compounds in cyclohexane and in benzene were measured and used in evaluating dipole moments of the solutes by means of the relations ${ }^{11}$

$$
\begin{align*}
P_{12} & =P_{1} c_{1}+P_{2} c_{2}=[(\epsilon-1) /(\epsilon+2)](M / d)  \tag{3}\\
P & =P_{\mathrm{A}}+P_{\mathrm{E}}+P_{\mu} \tag{4}
\end{align*}
$$

where $P$ is the polarization; $c$, the concentration in mole fraction; $\epsilon$, the static dielectric constant. The subscripts, 1,2 and 12 , refer to the solvent, solute and solution, respectively, while $P_{\mathrm{A}}, P_{\mathrm{E}}$ and $P_{\mu}$ designate the contribution to $P$ of the atomic, electronic and dipole orientation polarizations, respectively. In equation 3 , the value of $P_{2}$ used was ( ${ }_{\infty} P_{2}$ ), that obtained by extrapolating $P_{2}$ vs. $c_{2}$ to infinite dilution, while ( $\left.P_{\mathrm{E}}\right)_{2}$ was evaluated from equation 1 , using either $\phi_{\infty}$ or $\phi_{\mathrm{D}}$. $\left(P_{\mathrm{A}}\right)_{2}$ was estimated on the assumption that it was an additive bond property, as proposed by Sutton ${ }^{13}$ and LeFèvre ${ }^{14}$ for certain cases. The additivity of $P_{\mathrm{A}}$ was tested utilizing the values given in Table III. Since $P_{\mathrm{A}}$ is to be characteristic of a bond or atomic grouping, its value for decachlorobutane should be 2.5 times that for carbon tetrachloride, or 5 to 7.5 cc ; the value found from the relation ( $P_{\mathrm{A}}=P-P_{\mathrm{E}}^{\infty}$ ) was $5 \pm 2.5 \mathrm{cc}$. ; this agreement is within experimental error. The dipole moments listed in Table IV then were obtained (at $20^{\circ}$ ) using either (a)

$\mu_{\infty}=0.0127\left(P-P_{\mathrm{A}}-P_{\mathrm{E}}^{\infty}\right)_{2}$ or $(\mathrm{b}) \mu_{\mathrm{D}}=$ $0.0127\left(P-P_{\mathrm{E}}^{\mathrm{D}}\right)_{2}$ wherein $\left(P_{\mathrm{A}}\right)_{2}$ was negligible.

In two separate experiments, a check was made on the procedure outlined above; these gave for $\mu_{\mathrm{D}}$ for fluorobenzene: 1.45 and 1.52 D ; Wesson ${ }^{15}$ gives 1.45 and 1.58 D . The probable errors in the calculated quantities given in Tables II and IV are: $a \pm 0.005, \phi \pm 0.0005, c_{\mathrm{i}} \pm 0.015, P \pm 2.5 \mathrm{cc}$., and $\mu \pm 0.1 D$ if $\mu>1 D$ and $\pm 0.3 D$ if $P_{\mu}<5 \mathrm{cc}$.

## Discussion

The optical dispersion may be expressed by the equation ${ }^{12,16}$

$$
\begin{equation*}
\phi_{\lambda}=\left[\left(n_{\lambda}^{2}-1\right) /\left(n_{\lambda}^{2}+2\right)\right]=\sum_{j} f_{i \mathrm{i}} /\left(\nu_{\mathrm{ij}}^{2}-\nu^{2}\right) \tag{5}
\end{equation*}
$$

where $\phi_{\lambda}, n_{\lambda}$ and $\lambda$ are defined above; $\nu_{\mathrm{ij}}$ represents the characteristic frequencies for absorption, for the molecule making a transition between the states i and j ; $f_{\mathrm{ij}}$ is the corresponding "oscillator strength." If one selects a single term only from the sum in (5), he will obtain the dominant $\nu_{i j}$ or the corresponding $\lambda_{i}$ as used in (2). The values of $\lambda_{i}$ thus deduced are listed in Table II. The corresponding energies are in the far ultraviolet and are larger than those found for the ionization potentials (i.p.) of most organic compounds; typical values for halogenated compounds cited by Price, ${ }^{17}$ Walsh ${ }^{18}$ and Sugden ${ }^{19}$ correspond to transitions in the 1300 to $1500 \AA$. region. Since an i.p. measures a limiting $\mathrm{R} \leftarrow \mathrm{N}$ transition (Normal state of molecule $\rightarrow$ Rydberg type electronically excited state) and $\lambda_{i}$ represents a hypothetical $\mathrm{R} \leftarrow \mathrm{N}$ transition, one might expect that the energies of both will follow an order for the perhalocarbons similar to that for the partially chlorinated hydrocarbons. The order for the latter, with typical values of their i.p., is: (a) saturated compound, $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{Cl}, 10.89$ e.v., (b) vinyl compound, $\mathrm{C}_{2} \mathrm{H}_{3} \mathrm{Cl}, 10.0$ e.v., and (c) conjugated diene, chloroprene, 8.93 e.v. ${ }^{17}$ The justification for this sequence of the magnitudes of i.p. or in general for an energy interval in the $R \leftarrow N$ transitions of any similar series of compounds is given by Coulson ${ }^{20}$ and Price. ${ }^{17}$ An increase in the ionic character of a bond or molecule lowers the energy of the ground state of the ion and, con-

${ }^{a}$ Calcd. $\left(P_{\mathrm{E}}^{\mathrm{D}}\right.$ ) was obtained by using the following bond refractivities: $\mathrm{CF}, 1.82 ; \mathrm{CCl}, 6.48 ; \mathrm{C}=\mathrm{C}, 4.16 ; \mathrm{C}-\mathrm{C}, 1.296$; $\mathrm{C}-\mathrm{C}$ between two double bonds, 2.12 ; $\mathrm{CH}, 1.674$ (see text for source). ${ }^{b} \mathrm{~B}$ and C refer to measurements in benzene and cyclohexane, respectively. For the dipole moments which were calculated, the symbols employed were: $\mu_{\max }$, maximum dipole moment; $\mu_{\mathrm{min}}$, minimum dipole moment; $\mu_{\mathrm{FR}}$ is the free rotation moment. Where no $\mu_{\mathrm{FR}}$ is indicated, $\mu$ is independent of the angle of rotation. Where a particular isomer (i.e., cis-cis, etc.) is indicated, the calculated moments are for that particular stereoisomer.
sequently, that of the R states of the molecule more than the N state of the molecule. The i.p. and $1 / \lambda_{\mathrm{i}}$ should, therefore, shift to lower energies with an increase in ionic character of the molecule.
The dispersion data offer some information on the refractivities which may be assigned to individual bonds in the various compounds. Some of the conclusions which were drawn have already been anticipated in a forthcoming publication by Fainberg and Miller, ${ }^{21}$ so that our results complement theirs. Fainberg and Miller ${ }^{21}$ have shown by analysis of the $P_{\mathrm{E}}^{\mathrm{D}}$ of $M R_{\mathrm{D}}$ values of an extensive series of compounds that a consistent set of atomic refractivities, $A R_{\mathrm{D}}$, for perhalogenated hydrocarbons may be obtained. The best values they deduced are: C, 2.584, F, 1.165 and H, 1.029 ; however, one must assign values to the refractivities of the other halogens depending on their position on the carbon skeleton; they tabulated corrections for the variations in $A R_{D}$ with structure. The data cited in Tables V and VI indicate that the conclusions of Fainberg and Miller ${ }^{21}$ can be substantiated by evaluating the increment in $P_{\mathrm{E}}^{\mathrm{E}}$ upon substitution of Cl for H , or F for Cl , i.e., [ $P_{\mathrm{Cl}}-P_{\mathrm{H}}$ ] or $\left[P_{\mathrm{F}}-P_{\mathrm{Cl}}\right]$. The increinent in refractivity is a more reliable indication of the effect of substitution on bond refractivity than $P_{\mathrm{E}}^{\mathrm{D}}$ itself, because it does not depend on an arbitrary
(21) A. H. Fainberg and W. T. Miller (to be published).
choice of individual $A R_{\mathrm{D}}$. As shown in Table V , the values $\left[P_{\mathrm{Cl}}-P_{\mathrm{H}}\right]$ do vary significantly with atomic grouping in the molecule, while values of $\left[P_{\mathrm{Cl}}-P_{\mathrm{F}}\right]$ are suitably constant for substitution in perhalogenated propanes and butanes, Table VI. The only significant difference appears for $\mathrm{CCl}_{3} \mathrm{CClFCCl}_{2} \mathrm{~F}$ and cannot be explained in terms of a structural factor.

In the case of unsaturated compounds, the exaltation in $P_{\mathrm{E}}^{\mathrm{D}}$ is associated with variation in the contribution of the $\mathrm{V} \leftarrow \mathrm{N}$ transition due to the shift in $\lambda\left(V_{1} \leftarrow N\right)$. This contribution can be evaluated from (5), by using only the term involving $\lambda_{1}=\left(\mathrm{V}_{1} \rightarrow \mathrm{~N}\right)^{22}$ and defining the exaltation as $\Delta P_{\mathrm{E}}^{\mathrm{D}}=\left[P_{\mathrm{E}}^{\mathrm{D}}-\left(P_{\mathrm{E}}^{\mathrm{D}}\right)_{\mathrm{c}}\right]$, where $\left(P_{\mathrm{E}}^{\mathrm{D}}\right)_{\mathrm{c}}$ is obtained by using the values for the bond refractivities given in Table IV. One may write for $\Delta P_{\mathrm{E}}^{\mathrm{D}}=c^{2}\left[f_{\mathrm{ij}} /\left(1 / \lambda_{\mathrm{i}}^{2}-1 / \lambda^{2}\right)-f_{\mathrm{ijc}}\left(1 / \lambda_{\mathrm{ic}}^{2}-1 / \lambda^{2}\right)\right]$, where the term with subscript c refers to a regular double bond and the other term to the molecule in question. A plot of $\Delta P_{\mathrm{E}}^{\mathrm{D}}$ vs. $1 / \lambda_{\mathrm{i}}^{2}$ should be roughly linear if the $f_{\mathrm{ij}}$ 's are approximately equal. Figure 1 shows this relation for the $\lambda\left(\mathrm{V}_{1} \leftarrow \mathrm{~N}\right)$ transition in the s-cis form of the perchlorofluorobutadienes. Added to the plot are data for butadiene and chloroprene; the large departure of these points from the curve can in part be attrib-

${ }^{\text {a }} \Delta P_{\mathrm{B}}^{\mathrm{D}}$ represents the difference in the bond refractivities of carbon-chlorine and carbon-fluorine bonds. Using the value obtained in Table V for the carbon-chlorine bond refractivity, an average value of 1.75 was obtained for the car-bon-fluorine bond refractivity.
uted to the poor development of the s-cis band, making it difficult to identify the maximum wave length of absorption.

Dipole moments were obtained by reducing the polarization data as given above. A comparison then was made between the observed dipole moments ( $\mu_{\text {ous }}$ ) and those calculated by assuming
a consistent set of values for the CCl and CF bond moments, although these do depend on the molecular environment of the particular CF and CCl bonds, Table IV. For example, an estimate of $\Delta \mu(\mathrm{CF}-\mathrm{CCl})$ can be obtained either directly from the dipole moments of $\mathrm{CCl}_{3} \mathrm{~F}(0.48 D)^{15}$ and of $\mathrm{CF}_{3} \mathrm{CCl}_{2} \mathrm{~F}(0.53 D)^{15}$ or from the difference between the dipole moments of $\mathrm{CCl}_{3} \mathrm{H}(1.05 \mathrm{D})^{15}$ and $\mathrm{CF}_{3} \mathrm{H}(1.59 \mathrm{D}) .^{15}$ A reasonable value is $\Delta \mu(\mathrm{CF}-\mathrm{CCl})=0.5 D$ in a perhalogenated environment. In contrast an estimate of $\Delta \mu$ derived from the difference between $\mathrm{CH}_{3} \mathrm{~F}$ (1.81 $D)^{15}$ and $\mathrm{CH}_{3} \mathrm{Cl}(1.86 D),{ }^{15}$ in a non-perhalogenated environment, is at most 0.1 D . The corresponding value used for the CCl bond was that of $\mathrm{CCl}_{3} \mathrm{H}^{15}$ or 1.05 D . A test of the above assumptions was made by calculating $\mu$ for $\mathrm{CClF}_{2} \mathrm{CCl}_{2} \mathrm{~F}$ from the polarization data given by Fuoss ${ }^{23}$ : $P=34.5 \mathrm{cc}$. Using a value of $P_{\mathrm{A}}=6.5 \mathrm{cc}$. (that of $\mathrm{C}_{2} \mathrm{~F}_{6}$ ) and $P_{\mathrm{E}}=21.5 \mathrm{cc}$., calculated from bond refractivites, a value of $P_{\mu}=5.58 \mathrm{cc}$. or $\mu=0.53 D$ was obtained. Fuoss assumed that this molecule had a zero dipole moment, on the basis of the dipole moments of $\mathrm{CH}_{3} \mathrm{~F}$ and $\mathrm{CH}_{3} \mathrm{Cl}$ given above. Maximum, minimum and free rotation values of the dipole moment were also calculated and found to be 0.94, 0.0 and 0.68 D , respectively. A value of $\Delta \mu$ -$(\mathrm{CCl}-\mathrm{CF})=0.5 D$ is in agreement with $\mu=$ 0.52 D reported for $\mathrm{C}_{2} \mathrm{~F}_{5} \mathrm{Cl}$ by Di Giaconno and Smyth. ${ }^{24}$

The calculation of dipole moments of molecules from assigned bond moments on the assumption of specified configurations has been discussed by many investigators. ${ }^{25-27}$ For the perhalogenated butanes, the calculation was carried out as indicated. Values of $\Delta \mu(\mathrm{CCl}-\mathrm{CF})=0.5 D$ and $\mu$ $(\mathrm{CCl})=1.05 \mathrm{D}$ were assumed. The butane skeleton which may be represented as $\begin{array}{cc}\mathrm{C} & -\mathrm{C} \\ 1 & 2\end{array}$
$\qquad$
permits rotation around three bonds: (a) group 1 , with respect to 2 , (b) group 4 , with respect to 3 , and (c) groups 1 and 2 together, with respect to 3 and 4 together. The molecule was considered to be split into two ethyl fragments; the dipole moments for free rotation of group 1, with respect to 2 , and that of 4 , with respect to 3 , were calculated by resolving the moments of each group and assuming that the resultant moments rotated freely with respect to each other. Then these resultants were assumed to rotate freely with respect to each other around the $2,3 \mathrm{C}-\mathrm{C}$ bond. The minimum and maximum moments of the butanes reported were those corresponding to the minimum and maximum moments of the free rotation moments of the ethyl fragments. All bond angles were assumed to be tetrahedral.

All the butanes studied had dipole moments which were less than those expected for free rotation. This fact can be explained by assuming restricted rotation around each of the CC bonds,

Fig. 1.-The variation of the exaltation of molar refractivities with $\lambda_{i}{ }^{-2}=\lambda^{-2}\left(V_{1} \leftarrow N\right)^{29}$ for the s-cis form of some perchlorofluoro-1,3-butadienes: (a) butadiene, $P_{\mathrm{D}}$ $21.1,30\left(\mathrm{~V}_{1} \leftarrow \mathrm{~N}\right)^{30} 2288 \AA$.; chloroprene, $P_{\mathrm{D}} 2 \overline{5} .31,{ }^{31}\left(\mathrm{~V}_{1} \leftarrow\right.$ N) $2216 \AA .{ }^{32}$
since the free rotation dipole moments essentially measure the molecular moment when the dipoles are $90^{\circ}$ to each other; a dipole moment of less than this indicates restricted rotation with the molecule in the s-trans configuration.

In Table IV, there are also data for perhalogenated propylenes, butenes and butadienes. The propylenes and butenes which were studied were treated as substituted ethylenes, since all the compounds used had either a $\mathrm{Cl}, \mathrm{CCl}_{3}$ or $\mathrm{CF}_{3}$ group attached to a vinyl carbon atom. The moment of $\mathrm{CCl}_{3} \mathrm{CCl}=\mathrm{CCl}_{2}, \mu=0.45 \mathrm{D}$, is the difference in the dipole moments between a $\mathrm{CCl}_{3}$ group and a Cl atom attached to a perchlorinated vinyl radical. A corresponding difference $\mu(\mathrm{CF}-$ $\mathrm{CCl})$ attached to a vinyl carbon is given by the dipole moment of $\mathrm{CCl}_{2}=\mathrm{CClF}$, (ref. 27, p. 276) $0.4 D$. This is in agreement with the value used in calculating the results in Table IV.

That the dipole moment of $\mathrm{CF}_{3} \mathrm{CCl}=\mathrm{Cl}_{2}$, $1.07 D$, is a direct measure of the difference $\Delta \mu$ -$\left(\mathrm{CF}_{3}-\mathrm{CCl}\right)$ between the moment of a $\mathrm{CF}_{3}$ and Cl atom attached to a perchlorinated vinyl group is of special interest. The butenes reported in Table IV were mixtures of cis-trans isomers; hence, the observed moments gave some indication of the isomeric composition. For example, the observed moment of octachlorobutene, 0.39 D , indicates that the sample used was a mixture of cis-trans butene-2 and of butene-1. The sample of $\mathrm{CF}_{3} \mathrm{CCl}=\mathrm{CClCF}_{3}$ used was a mixture of cistrans isomers, and the dipole moment indicated that the probable composition of the mixture was $50 \%$ cis and $50 \%$ trans.

The data given in Table IV for the perhalogenated butadienes can be related to the composition of the samples used and to their molecular configurations. Suppose we accept the value of $P_{\mu}=0$ for $\mathrm{CCl}_{2}=\mathrm{CClCCl}=\mathrm{CCl}_{2}$; then $P_{\mathrm{A}}=$ 5.0 cc ., as noted in Table IV, is obtained; this was

Fig. 2.-The spatial relation between two dipoles with partial free rotation; $\alpha$ is the angle between the dipole and the $x-y$ plane, and $\theta$ is the angle between two dipole rotating with respect to each other
then used in estimating the moments of other perhalogenated butadienes. The measured moment $(1.02 \mathrm{D}$ ) for $\mathrm{CFCl}=\mathrm{CClCCl}=\mathrm{CClF}$ appears anomalous because the sample was a mixture of isomers and should have had a moment less than the estimated maximum, 0.95 D . In contrast, the observed moment of $\mathrm{CF}_{2}=\mathrm{CClCCl}=\mathrm{CFCl}(0.0 \mathrm{D})$ indicates that it was predominantly a trans isomer, while that of $\mathrm{CClF}=\mathrm{CFCF}=\mathrm{CClF}(1.0 \mathrm{D})$ indicates that it is predominantly a mixture of ciscis and trans-trans isomers.

The measured dipole moment of $\mathrm{CF}_{2}=\mathrm{CClCCl}=$ $\mathrm{CF}_{2}(0.37 \mathrm{D})$ provided an opportunity to estimate the potential barrier restricting rotation about the single bond in this molecule; i.e., the interconversion of the s-trans,
 forms.

If a potential function restricting rotation is assumed similar to that postulated by Aston, ${ }^{28}$ et al., for butadiene, in accounting for their thermodynamic data

$$
\begin{align*}
& V=V_{0} / 2[1-\cos 2(\theta-\pi] \text { for } \pi / 2 \leqslant \theta \leqslant \pi  \tag{6a}\\
& V=V_{0} / 2+V_{0} / 4[1-\cos 2 \theta] \text { for } \quad 0 \leqslant \theta \leqslant \pi / 2 \tag{6b}
\end{align*}
$$

then $V_{0}$ may be estimated from the measured dipole moment of the perhalobutadiene. $\theta$ is defined as the angle between the two planes, each containing one of the resultant moments of a vinyl group and the common axis of rotation, Fig. 2. The resultant moment of each half of the molecule is $0.5 D$, and each makes an angle $\alpha_{1}=$ $\alpha_{2}=109^{\circ}$ with the axis of rotation. The square of the total dipole moment is given by

$$
\begin{equation*}
\mu^{2}=A+B \cos \theta \tag{7}
\end{equation*}
$$

If $\mu_{1}$ and $\mu_{2}$ were two unequal dipoles rotating with respect to each other

$$
\begin{align*}
& A=\mu_{1}^{2}+\mu_{2}^{2}-2 \mu_{1} \mu_{2} \cos \alpha_{1} \cos \alpha_{1}  \tag{8a}\\
& B=2 \mu_{1} \mu_{2} \operatorname{sil1} \alpha_{1} \sin \alpha_{2}
\end{align*}
$$

[^2] 220 (1940)

For the case considered, $\alpha_{1}=\alpha_{2}=109^{\circ}, B=$ $A=(16 / 9) \mu^{2}$, and the average of the square of the dipole moment is

$$
\begin{equation*}
\overline{\mu^{2}}=\frac{\int_{0}^{\pi} \mu^{2}(\theta) \exp [-V(\theta) / R T] \mathrm{d} \theta}{\int_{0}^{\pi} \exp [-V(\theta) / R T] \mathrm{d} \theta} \tag{9}
\end{equation*}
$$

Substitute into (7)

$$
\begin{align*}
\overline{\mu^{2}} & =A+B f \\
f & =\frac{\int_{0}^{\pi} \cos \theta \exp [-V(\theta) / R T] \mathrm{d} \theta}{\int_{0}^{\pi} \exp [-V(\theta) / R T] \mathrm{d} \theta} \tag{10}
\end{align*}
$$

Evaluation of (8) and substitution into (10) gave $B=A=0.44, f=0.69$. With $a=$ ( $V_{0} /$ $2 R T$ ) and $T=293^{\circ} \mathrm{K}$.

$$
0.69=\frac{e^{-a / 2} \int_{0}^{\pi / 2} \exp [(a / 2) \cos 2 \theta] \cos \theta \mathrm{d} \theta+\int_{\pi / 2}^{\pi} \exp [a \cos 2(\theta-\pi)] \cos \theta \mathrm{d} \theta}{e^{-a / 2} \int_{0}^{\pi / 2} \exp [(a / 2) \cos 2 \theta] \mathrm{d} \theta+\int_{\pi / 2}^{\pi} \exp [a \cos 2(\theta-\pi)] \mathrm{d} \theta}
$$

butadiene, ${ }^{28}$ which was 5 kcal., although it is expected to be larger due to the enhanced interaction between halogen atoms as contrasted to the hydrogen atoms.

The ratio of the number of molecules in the trans configuration to those in the cis configuration is given by $N_{\text {trans }} / N_{\text {cis }}=\exp (-a)=12.9$, while the ratio of the number of molecules $N_{t} / N_{c}$, with $\theta$ in the interval $0 \leqslant \theta \leqslant \pi / 2$, to those with $\theta$ in the interval $\pi / 2 \leqslant \theta \leqslant \pi$ is given by

$$
\begin{equation*}
N_{t /} / N_{c}=\frac{\int_{0}^{\pi / 2} \exp [a \cos 2(\theta-\pi)] \mathrm{d} \theta}{e^{-a / 2} \int_{\pi / 2}^{\pi} \exp [(a / 2) \cos 2 \theta] \mathrm{d} \theta}=7.8 \tag{12}
\end{equation*}
$$

# Thermodynamics of Aqueous Ferricyanide, Ferrocyanide and Cobalticyanide Ions 

By Loren G. Hepler, ${ }^{1}$ John R. Sweet and Richard A. Jesser<br>Received June 8, 1959

We have measured heats of solution of $\mathrm{K}_{3} \mathrm{Fe}(\mathrm{CN})_{6}(\mathrm{c})$ and $\mathrm{K}_{3} \mathrm{Co}\left(\mathrm{C} . \mathrm{V}_{6}(\mathrm{c})\right.$ and the solubility of $\mathrm{K}_{3} \mathrm{Co}(\mathrm{C} .)_{6}(\mathrm{c})$ in water at $25^{\circ}$. The resulting data have been used in calculating that the standard partial molal entropies of $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{-3}(\mathrm{aq})$ and $\mathrm{Co}-$ $(\mathrm{CN})_{6}{ }^{-3}(\mathrm{aq})$ are 63.4 and 55.7 cal. $/ \mathrm{deg}$. mole, respectively. The heat of oxidation of $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{-4}(\mathrm{aq})$ by $\mathrm{Br}_{2}(\mathrm{liq})$ was measured and used with the above entropy of $\left.\mathrm{Fe}_{(\mathrm{CN}}\right)_{6}{ }^{-3}(\mathrm{aq})$ to obtain $17 \mathrm{cal} . / \mathrm{deg}$. mole for the standard partial molal entropy of $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{-4}(\mathrm{aq})$. The uncertainty in the entropy of $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{-4}(\mathrm{aq})$ is large, mainly because of the uncertainty of the oxidation potential used in the calculation. Heats of solution of $\mathrm{K}_{4} \mathrm{Fe}(\mathrm{CN})_{6}(\mathrm{c})$ and $\mathrm{K}_{4} \mathrm{Fe}(\mathrm{CN})_{8} \cdot 3 \mathrm{H}_{2} \mathrm{O}$ (c) also were measured. The as yet undetermined Third Law entropies of $\mathrm{K}_{4} \mathrm{Fe}(\mathrm{CN})_{6}(\mathrm{c})$ and $\mathrm{K}_{4} \mathrm{Fe}(\mathrm{CN})_{6} \cdot 3 \mathrm{H}_{2} \mathrm{O}$ (c) can be combined with data now available to give a reliable thermodynamic value for the standard oxidation potential of the ferrocyanide-ferricyanide couple.

Stephenson and Morrow ${ }^{2}$ have investigated the heat capacities of $\mathrm{K}_{3} \mathrm{Fe}(\mathrm{CN})_{6}(\mathrm{c})$ and $\mathrm{K}_{3} \mathrm{Co}(\mathrm{CN})_{6}$ (c) from 15 to $300^{\circ} \mathrm{K}$. and have calculated entropies at $298.16^{\circ} \mathrm{K}$. They used the standard entropy of $\mathrm{K}_{3} \mathrm{Fe}(\mathrm{CN})_{6}$ (c) with thermodynamic data from the literature in calculating the standard partial molal entropy of $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{-3}(\mathrm{aq})$ and other derived thermodynamic quantities. They also pointed out the approximate nature of these derived quantities and suggested that careful determination of some heats of solution would be desirable. ${ }^{3}$
Heats of solution of $\mathrm{K}_{3} \mathrm{Fe}(\mathrm{CN})_{6}(\mathrm{c}), \mathrm{K}_{4} \mathrm{Fe}(\mathrm{CN})_{6}$ (c), $\mathrm{K}_{4} \mathrm{Fe}(\mathrm{CN})_{6} \cdot 3 \mathrm{H}_{2} \mathrm{O}$ (c) and $\mathrm{K}_{3} \mathrm{Co}(\mathrm{CN})_{6}$ (c) and the heat of oxidation of $\mathrm{Fe}(\mathrm{CN})_{6}{ }^{-4}(\mathrm{aq})$ to $\mathrm{Fe}-$ $(\mathrm{CN})_{6}{ }^{-3}(\mathrm{aq})$ by $\mathrm{Br}_{2}$ (liq) were measured. The

[^3]solubility of $\mathrm{K}_{3} \mathrm{Co}(\mathrm{CN})_{6}(\mathrm{c})$ in water at $25^{\circ}$ was also determined.

## Experimental

The solution calorimeter used in this investigation has been described previously. ${ }^{4,5}$ All of our heat determinations were at $25.0 \pm 0.3^{\circ}$ with 950 ml . of water or solution in the calorimeter.
Commercial C.P. $\mathrm{K}_{3} \mathrm{Fe}(\mathrm{CN})_{6}$ (c) was purified according to the method of Stephenson and Morrow. ${ }^{2}$ Baker "Purified" $\mathrm{K}_{4} \mathrm{Fe}(\mathrm{CN})_{6} \cdot 3 \mathrm{H}_{2} \mathrm{O}(\mathrm{c})$ was recrystallized three times from distilled water. Aqueous solutions of $\mathrm{K}_{4} \mathrm{Fe}$ $(\mathrm{CN})_{6}$ were never heated above $60^{\circ}$. Anhydrous $\mathrm{K}_{4} \mathrm{Fe}-$ $(\mathrm{CN})_{6}(\mathrm{c})$ was obtained by drying the recrystallized trihydrate at $110^{\circ}$ or by prolonged drying over $\mathrm{P}_{2} \mathrm{O}_{5}$ in a vacuum desiccator. No significant differences in analysis or heats of solution of $\mathrm{K}_{4} \mathrm{Fe}(\mathrm{CN})_{6}(\mathrm{c})$ samples prepared in these two ways were noted.
Two samples of $\mathrm{K}_{4} \mathrm{Fe}\left(\mathrm{CN}_{6} \cdot 3 \mathrm{H}_{2} \mathrm{O}\right.$ (c) for heat of solution measurements were prepared. One sample was prepared by storing damp, recrystallized $\mathrm{K}_{4} \mathrm{Fe}(\mathrm{CN})_{8} \cdot 3 \mathrm{H}_{2} \mathrm{O}$ (c) in a black-
