

Page 5799. The authors wish to report further: "On repeating the experimental work, R. J. Steltenkamp obtained somewhat different results. The principal ethoxyacetylene adduct (b.p.  $107^\circ$  (3 mm.),  $n_D^{25}$  1.5500; hydrolysis gave *p*-toluenethiol and no dinitrophenylhydrazone of *p*-tolylmercaptoacetaldehyde; aniline gave *N,N'*-diphenylacetamide, m.p.  $131$ – $132.5^\circ$ ) is different from  $C_7H_7SCH=CHOEt$  prepared independently from *cis*- $C_7H_7SCH=CHCl$  (fair conversion), from  $C_7H_7SCH_2CH(OEt)_2$  (poor conversion) and *via* the very clean free-radical addition of  $C_7H_7SH$  to ethoxyacetylene (b.p.  $102^\circ$  (0.55 mm.),  $n_D^{25}$  1.5640; yielded the dinitrophenylhydrazone of *p*- $C_7H_7SCH_2CHO$ ). Hence the principal initial ethoxyacetylene adduct under Goldhamer's conditions is  $CH_2=C(OEt)SC_7H_7$  and not *cis*- $C_7H_7SCH=CHOEt$ . This initial adduct shows essentially one peak on a gas chromatogram (one of the two minor peaks comes from  $CH_2COSC_7H_7$ ), but on standing this peak becomes minor and several others appear, the major one of which derives from  $C_7H_7SCH=CHOEt$ , and another from  $C_7H_7SH$ . Presumably the initial 1,1-adduct reverts to starting materials, which recombine in a free radical process."—WILLIAM E. TRUCE.
