BOOK REVIEWS

Nouveau Traité de Chimie Minérale. Tome VII. Scandium, Yttrium. Éléments des Terres Rares. Actinium. (2 Fascicules). Edited by PAUL PASCAL. Masson et Cie., 120, Boulevard Saint-Germain, Paris 6, France. 1959. xxxix + 1473 pp. 17.5 × 26 cm. Price, brochés, 180 NF; cartonnés toile, 200 NF.

Some 27 years ago the original "Traité de Chimie Minérale," published under the direction of Professor Paul Pascal, treated the chemistry of those rare earth elements known at that time as completely as possible.

Obviously during the interim between that publication and the present an extensive amount of research on these elements has been done. The next development was to collect the data and ideas and compile them into one compact source. Such has been done in Volume VII of the Nouveau Traité. So great has been the amount of research that this volume has had to be published in two parts.

The form is similar to the old Traité but far more extensive: Part 1 (706 pages) begins with general statements regarding the rare earth elements scandium and yttrium and then deals with the history of these elements, which is most complete and well authenticated. This part is unusually well done. The remainder of this part of Volume VII is given over to the treatment of the various ores and the separation of the elements themselves plus the physical properties of the metals. Several such methods are given. Many specific separations are outlined. Limitations are pointed out in the various methods of separating the salts in a mixture. These separations range from the divalent state of the ions to complex ions. Even industrial separations are outlined. Schematic drawings of the processes are given.

The last section of this part of Volume VII, dealing with the physical properties of the metals themselves, is particularly well done and most inclusive. Several pages are given over to these properties of each rare earth in its elemental state. On reading this volume one will be surprised to find many useful thermodynamic data available, from specific heats to the Gibbs function. Important electrical properties are also discussed.

Part 2 (740 pages) deals with the chemical properties of the metals and their salts, including methods of analysis for the cations. Much is also done with the alloys of the rare earths with other metals. This part of the book contains many two-component melting point diagrams. One ternary diagram, Fe-Al-Ce, is included.

Nuclear properties of the radioactive isotopes of the lanthanides along with their uses in the domains of physical chemistry, biology and medicine are fairly thoroughly treated.

The section devoted to detection of and analysis for the cations of the rare earths is outstandingly well done and highly specific. Pitfalls are pointed out in the various analytical procedures. Both chemical and physical analytical methods are treated. Fairly complete data on absorption spectra and flame spectra for these lanthanides are given.

This volume, all in all, is very well done, and is probably the most comprehensive work on scandium, yttrium and the lanthanides yet printed.

FREDERIC C. SCHMIDT

Handbuch der Präparativen Anorganischen Chemie Zweite umgearbeitete Auflage. Erster Band. Edited by GEORG BRAUER, o. Professor für anorganische Chemie an der Univ. Freiburg i. Br. Ferdinand Enke Verlag, Hasenbergsteige 3, Stuttgart W. Germany. 1960. xiii + 884 pp. 16.5 × 24.5 cm. Price, Geheftet DM., 118.00; Ganzleinen DM. 124.00.

Chapter I contains one hundred and twelve useful pages on preparative methods, with ninety-one diagrams and sixteen tables. Authors Schenk and Brauer cover the topics glass, ceramic materials, metals, purification of mercury, electric furnaces, temperatures, high vacuum techniques, gases and purification of compounds.

Chapter II, in eighteen sections with seven hundred and sixty-six pages and one hundred and eighty-nine diagrams total, describes more than seven hundred and fifty detailed preparations of compounds and elements and indicates preparative methods for almost twelve hundred compounds and elements. The coverage includes hydrogen and all the elements of the seven regular groups in the Periodic Table except francium, radium, polonium and astatine. These authors include silver(I) fluoride as a derivative of fluorine. Much credit is due the thirteen authors of individual sections: Baudler, Becher, Dönges, Ehrlich, Fehér, Glemser, Hofmann, Klement, Kwasnik, Rüdorff, Schenk, Schmeisser and von Wartenberg. This reviewer selects the following as twenty typical preparations: AgF₂, AlCl₃·SO₂, BiF₃, CaCN₂, CF₃I, DBr, EuF₂, F₂O, GeH₄, HCl₄·4H₂O, InCl, KIBr₂, KSO₂F, LiAl(CN)₄, NH₄PF₆, (PNCl₂)_n, Pb(C₂H₅)₄, SO₂ClF, Si₂OC₂H₅ and TiOCOH.

In the foreword Editor Brauer considers the experimental descriptions reliable because of information from the laboratories of the authors or from other laboratories. An eight page formula index is at the end of Volume I. A future Volume II on the transitional elements will complete the book.

Some minor weaknesses are always inevitable. Careful fractional distillation receives little attention in either chapter. Preparation of tetrafluorosilane should employ either fluorosilicic and concentrated sulfuric acids, as in the book, or the heating of barium fluorosilicate. Page 291 could mention that a mixture of perchloric and concentrated sulfuric acids oxidizes moderate amounts of organic matter smoothly. Also, phosphorus and iodine (in the ratio one to five atoms, respectively) react with water to yield hydrogen iodide quite satisfactorily, with adequate drying by passage over a long tube of phosphorus pentoxide. Formulas are subject to slight improvement sometimes: Ga[GaCl₄] and
